If we accept the postulate that the excess Ir is derived from impact of a 10-km diameter asteroid with Type 1 chondritic composition[2] our Ir data can be used to estimate the fraction of the kaolinitic bed contributed by the asteriod itself. The total integrated Ir under the anomaly peak, expressed as a surface density, was divided by the measured surface density of the kaolinitic clay layer to give the concentration of the Ir in the layer (with the assumption that all the Ir came in with this layer), and comparison of this concentration with that for a Type I chondrite yielded the asteroid contribution. This contribution ranged from 0.6 to 2.5% for the five Raton Basin sampling sites. The corresponding contributions for the Gubbio and Stevns Klint K–T anomaly clays have been reported[28] to be 1.6% and 21%, respectively. If we exclude major contributions from nearby volcanic eruptions and aeolian material, the remainder ($\geq$97.5%) of the Raton Basin K–T clay layer can be assigned to ejecta from the impact. The elemental abundances of the lithophiles Sc, Ti and Cr, therefore, reflect the composition of the impact site. Our data are best fitted by ejecta from basalts. The La/Yb ratio is high for oceanic basalt, but could have been made up by contribution from overlying sediments.

From our elemental abundance data we are unable to conclude whether or not the palynological K–T boundary is synchronous with the marine boundary, but there exist palaeomagnetism measurements bearing on this question. The palaeomagnetic polarity sequence for marine rocks has now been established for the late Cretaceous through the early Tertiary[29,30], and during the boundary period the polarity was reversed. However, Payne *et al.*[31], measuring samples taken from the K–T boundary zone in the Raton Basin, have reported normal polarity. More recent measurements on samples from the same sites and others in the Raton Basin by Shoemaker *et al.*[32] lead to assignment of reversed polarity. The latter work emphasizes that the polarity assignment is critically dependent on the removal of the strong normal overprint from the palaeomagnetic signals observed in near-boundary-level rocks in the Raton Basin.

The recent investigations at the K–T boundary in Montana have provided some clues to the synchronism of the two continental K–T boundary sequences. We have already pointed out that the elemental abundance patterns for Raton and Montana are similar and that the Cretaceous pollen *Proteacidites* disappears precisely at the top of the kaolinitic boundary clay. Also, Archibald *et al.*[33] have found that the Montana boundary zone lies in a stratigraphical sequence with reversed palaeomagnetic polarity. The highest dinosaur fossil horizon reported[34] in this region of Montana occurs ~3 m below the palynological K–T boundary and Ir anomaly, but a statistical analysis of the '3-m gap' data shows[24] that one cannot conclude that the dinosaurs disappeared before the Ir layer was deposited.

The body of information we have derived from the elemental abundances, clay mineralogy, stratigraphy and pollen data lead us to the following conclusions:

(1) The Ir-bearing kaolinite-rich clay bed at all the sampling sites resulted from fallout from a common source, and the excess Ir is associated primarily with the fallout and not with chemical concentration of pre-existing amounts in the local medium.

(2) The excess Sc, Ti, V, Cr and possibly Hf appear also to have come with the fallout and not from local enrichment processes. This enrichment pattern is consistent with the patterns observed in basalts.

(3) Although the kaolinite precursor material was deposited on several different local surfaces, in each case it is now overlain by a thin coal bed. This mode of deposition may simply be an indication that quiet swamp conditions preceding coal formation were a favoured environment for the preservation of this fallout material.

(4) The narrowness of the Ir distribution and the relatively small variation in surface density (a factor of four) indicate that the Ir has not undergone any large scale migration, but may have spread locally from the clay layer into the adjacent material.

(5) The uniformity in thickness of the K–T kaolinitic clay bed over a distance of at least 1,200 km indicates that the fallout material came from a common source at a considerable distance.

(6) Although the boundary clay bed may contain some altered volcanic ash or aeolian material, such contribution to the excess Ir does not appear to be significant.

We are indebted to the Los Alamos National Laboratory Reactor Group for performing the neutron irradiations and for deriving chemical abundance data for about 24 trace elements, and to L. R. Quintana for assistance with sample preparation and data reduction. We thank J. J. Connor and J. R. Hatch for critical comments. J.S.G., J.D.K. and C.J.O. thank the US Department of Energy for support.

Coupled Sm–Nd and U–Pb systematics in late Caledonian granites and the basement under northern Britain

A. N. Halliday

Scottish Universities Research and Reactor Centre, East Kilbride, Glasgow G75 0QU, UK

The British late Caledonian granites display a close correspondence between inherited U–Pb systematics in zircons and initial ε_{Nd} indicating that both were controlled by the age of a major component of continental crust. The data confirm and refine previous models of a basement comprising young crust in the south which includes arc and oceanic crust scrapings and progressively older continental crust northwestwards across Scotland.

MUCH recent research effort and speculation has been concentrated on the origin of granites, and Nd isotope geochemistry has played a key role in this research[1–5]. The Caledonian granites of the British Isles are of particular interest in this respect for several reasons. First, they are classical and as internationally recognized examples it is important that their genesis is properly understood. Second, there is a good background of reconnaissance chemical and isotopic data. Third, the Caledonian granites are not easily related to active subduction and there is no obvious mechanism for their generation. Finally they are by far the largest samples of what the lower crust was like at 400 Myr and their isotope geochemistry can tell us a great deal about the regional deep geology of the British Isles.

Pidgeon and Aftalion[6] discovered a marked Pb isotopic memory in zircons extracted from late Caledonian granites north of the Highland Boundary Fault (Fig. 1) which is absent from zircons from granites to the south. This has been interpreted as reflecting a contrast in basement to the north and south[6]. Pb, Sr, O and Nd isotopic data has confirmed the importance of continental crust in the generation of these granites[8–10]. In particular, O and Sr isotopic compositions plot with a broad correlation between the fields for mantle and crust reservoir types[8,10,11] suggesting overall interaction between mantle-like and crust-like reservoirs during magmatism. The common Pb isotopic compositions generally become more radiogenic southwards implying the southerly diminution of old granulite facies material in the crust[9,12].

Despite the large amount of isotopic data available there has been considerable controversy over the origin of the late Caledonian granites. Some authors have argued that the granites were largely derived from mantle, especially those lacking inherited zircons and with low initial $^{87}Sr/^{86}Sr$ (refs 13–16), others have proposed crustal source regions[4,6,7,17] and still other mixed origins but involving mantle or mafic lower crust[8,10,11,18]. Some of these views have been discussed elsewhere[19].

New Nd isotopic data are now presented which expand the previous data base[4]. From this it is concluded that although a mantle component is important, the lower and middle continen-

All isotopic analyses were performed using a fully automated V.G. Isomass 54E mass spectrometer except that $(^{87}Sr/^{86}Sr)_t$ marked (*) and all $^{87}Rb/^{86}Sr$ ratios except those of Garabal Hill and Distinkhorn (which are new determinations) are from refs 8 and 11. Ion exchange techniques were similar to those of O'Nions *et al.*[39]. $^{143}Nd/^{144}Nd$ and $^{87}Sr/^{86}Sr$ are normalized to $^{146}Nd/^{144}Nd = 0.7219$ and $^{88}Sr/^{86}Sr = 8.37521$ respectively. Bulk-Earth parameters used to calculate ε values are $^{143}Nd/^{144}Nd = 0.512636$, $^{147}Sm/^{144}Nd = 0.1967$, $^{87}Sr/^{86}Sr = 0.7045$, $^{87}Rb/^{86}Sr = 0.0839$. The $^{143}Nd/^{144}Nd$ of BCR-1 is 0.512633 ± 12 and $^{87}Sr/^{86}Sr$ of NBS 987 is 0.710275 ± 7 on the V.G. Isomass 54E at SURRC.

tal crust have affected the isotopic compositions to the extent that a change in the age of the basement is recognizable across the Grampian Highlands.

Nd isotopic data

Sm–Nd isotopic analyses of samples from 18 plutons, together with three Southern Uplands Lower Palaeozoic sediments, are presented in Table 1. Techniques have been presented elsewhere[20] and are summarized in Table 1. Many of the Sr isotopic analyses in Table 1 have been presented before[8,11] but some are new determinations of higher precision. The initial ε_{Nd} data are plotted geographically in Fig. 1 together with those of Hamilton *et al.*[4].

It is immediately apparent that nearly all the Caledonian granitic magmas had negative initial ε_{Nd} values the range being from +1.3 to −13.3. This situation can be compared with that of the coeval I and S type granitoids of the Lachlan fold belt, south-east Australia where the initial ε_{Nd} values have been reported as ranging between +4.4 and −9.8 (refs 5, 21). It appears that the range of initial Nd isotopic compositions in the British Caledonian granitoids is displaced to less radiogenic values by ~3 ε_{Nd} units. The British Caledonian granites can also be contrasted with the younger granitic magmas from convergent plate margins such as the Sierra Nevada[2,3], the Andes[1], and the Transhimalayan Belt[22], all of which are of Mesozoic–Tertiary age and which include substantial associated plutonics with high ε_{Nd}.

The only British intrusions with (just) positive initial ε_{Nd} are Cluanies and Strontian in the Northern Highlands, Kilmelford in the Grampian Highlands and Distinkhorn in the Midland Valley. Very negative initial ε_{Nd} values (<−6) are restricted to the Scottish Highlands (Fig. 1). Thus the Nd isotope systematics display parallels with common Pb and U–Pb zircon systematics in showing differences from north to south across northern Britain[6,9]. In contrast the Sr and O isotope systematics show no such simple geographical zonation[8,10]. The variation in ε_{Nd} could be due to changes in the mantle across Scotland as has been suggested for some of the cogenetic Devonian volcanics[23], greater crustal assimilation in the north or assimilation of different kinds of crust. This is best investigated by combining the Nd data with those of other isotopic systems.

Coupled Sm–Nd and U–Pb systematics

In Fig. 2 the ε_{Nd} values of the Newer granites for which zircon data are available are plotted. The shaded boxes represent granites with marked inherited zircon components and it is clear that an approximate cutoff of −6 in ε_{Nd} generally demarcates the boundary between granites with inherited zircons and those without. Several points arise from this.

(1) As the inherited zircons are unequivocally derived from the continental crust the lower ε_{Nd} values are also a function of crustal contamination or melting.

(2) Granites such as Hill of Fare, Lochnagar, Cruachan which contain little or no inherited zircon, but which lie in the Scottish Highlands, also have high ε_{Nd}. That is, the lack of inherited zircons is not a function of their loss by restite separation, but of a different source region.

(3) The Aberdeen and Findhorn granites are thought to be >~440 Myr in age[8,24] and their low ε_{Nd} values and inherited zircons reflect a dominance of old crustal components expected from magmas which were emplaced relatively soon after the climax of high-temperature metamorphism in that area. This accords with the findings of Hamilton *et al.*[4] for the Strichen and Longmanhill intrusions of similar age and setting.

(4) Excluding Findhorn and Aberdeen, a boundary to the limit of ε_{Nd} values of <−6 can be placed through the middle of the Grampian Highlands (Fig. 1). Hereafter this line is called the Mid-Grampian Line.

(5) The Strontian Complex lacks inherited zircons in its outer more mafic parts but contains zircons with a marked memory in the central biotite granite[6,8]. The ε_{Nd} values correlate with this in that they are close to bulk Earth in the outer parts but −6.3 in the biotite granite[4].

Nd–Sr–O isotopic relationships

In Fig. 3, initial ε_{Nd} is plotted versus initial ε_{Sr} for all the Caledonian granites analysed. There is no correlation between initial ε_{Nd} and initial ε_{Sr}. The >440-Myr granites plot to the

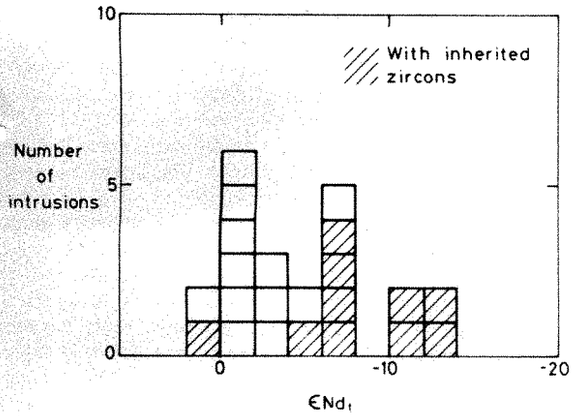

Fig. 2 Histogram of ε_{Nd_t} for all the post-tectonic granite intrusions for which zircon data are available. Shaded boxes are granites with inherited zircons. Data from this study and refs 4, 6, 8.

right with very radiogenic Sr. Moinian or Dalradian assemblages (largely comprising late Proterozoic metasediments) would be suitable crustal components for these magmas[8,25,26]. Some of the granites with inherited zircons plot towards the field of Lewisian crust. Granitic complexes such as Ross of Mull and Ratagain situated very close to the exposed Lewisian and with low ε_{Nd} probably contain a large component of Lewisian crust. However, many of the granites north of the Mid-Grampian Line have exceedingly high Sr contents[8,27] such that assimilation of Moinian or Dalradian assemblages (with low Sr concentrations) would change the ε_{Nd} value towards that of the contaminant more than would be detectable in ε_{Sr}. From this reconnaissance study such a process cannot be ruled out.

The Cluanies granodiorite is anomalous in having low ε_{Sr} and high ε_{Nd} but a marked inherited zircon component. The simplest explanation of this is that it is derived from old light rare-earth elements (LREE)-depleted crust. Some of the more mafic Lewisian granulites might be a suitable source[28].

The granites without inherited zircons plot between mantle-like compositions close to bulk Earth and the field of Southern Uplands Lower Palaeozoic sediments. It has been shown elsewhere that these sediments had Pb and Sr isotopic compositions that were similar to many of the Caledonian granites[8,9,11,41]. They also have the required paucity of Pb isotopic memory in the zircons such that melting or assimilation of these sediments (unlike those of the Moinian or Dalradian) would not greatly affect the zircon U–Pb systematics in the granites[8]. This is important because there is no doubt that these granites have interacted greatly with the continental crust as shown by their Sr and O isotopic signatures[10,11].

In Fig. 4, the initial ε_{Nd} values are plotted against $\delta^{18}O$ values given elsewhere[10,11]. Two samples are ^{18}O-depleted which is thought to be due to high temperature interaction with meteoric waters at their sub-volcanic emplacement level[10]. The Helmsdale granite has high $\delta^{18}O$ which has been attributed to late low-temperature fluid interaction[29]. In contrast the remaining granites have all been regarded as recording magmatic oxygen isotopic compositions, which correlate with initial ε_{Sr} but can be seen to be uncorrelated with initial ε_{Nd}. However, if the granites with no inherited zircons are considered alone, an inverse correlation is evident—the data points lying between values expected for a depleted mantle source ($\delta^{18}O \sim 6.0‰$, $\varepsilon_{Nd} > 0$) and the values for the Southern Uplands acid-clast Lower Palaeozoic sediments. This field of data includes the Strontian granodiorite from the Northern Highlands and samples from Lochnagar, Hill of Fare, Garabal Hill and Distinkhorn—all to the north of the Southern Uplands Lower Palaeozoic sediments. It can be seen that Dalradian metasediments (in which these last granites are situated) are not a major constituent of the source. The field also includes the Southern Uplands granites themselves plus those of the Lake District. The S-type[30] granites, Eskdale, Fleet and central Criffell all have high $\delta^{18}O$ (>10.0‰) and slightly lower ε_{Nd} (<−2). The outer part of Criffell has higher ε_{Nd} consistent with previous hypotheses that the Sr and O isotopic zonation of the pluton is due to interaction with Palaeozoic sediment or its melt derivatives[11,31–33]. The Shap granite has I-type mineralogy but high $\delta^{18}O$ and ε_{Sr} similar to the values for the S-type Eskdale intrusion. The difference in ε_{Nd} is consistent with the hypothesis that crustal metasomatic fluids have affected the Shap granite and modified its Sr and O isotopic compositions.

The granites from the north of the Mid-Grampian Line exhibit a limited range of $\delta^{18}O$ and no correlation with ε_{Nd}. This is hardly surprising as old high-grade metasedimentary rocks such as comprise the local geology commonly have lower $\delta^{18}O$ values than those of lower grade. Therefore , in general terms, it is to be expected that $\delta^{18}O$ will correlate with $^{87}Sr/^{86}Sr$ as observed because high grade metamorphic rocks will be depleted in Rb as well as having relatively low $\delta^{18}O$. In contrast high-grade

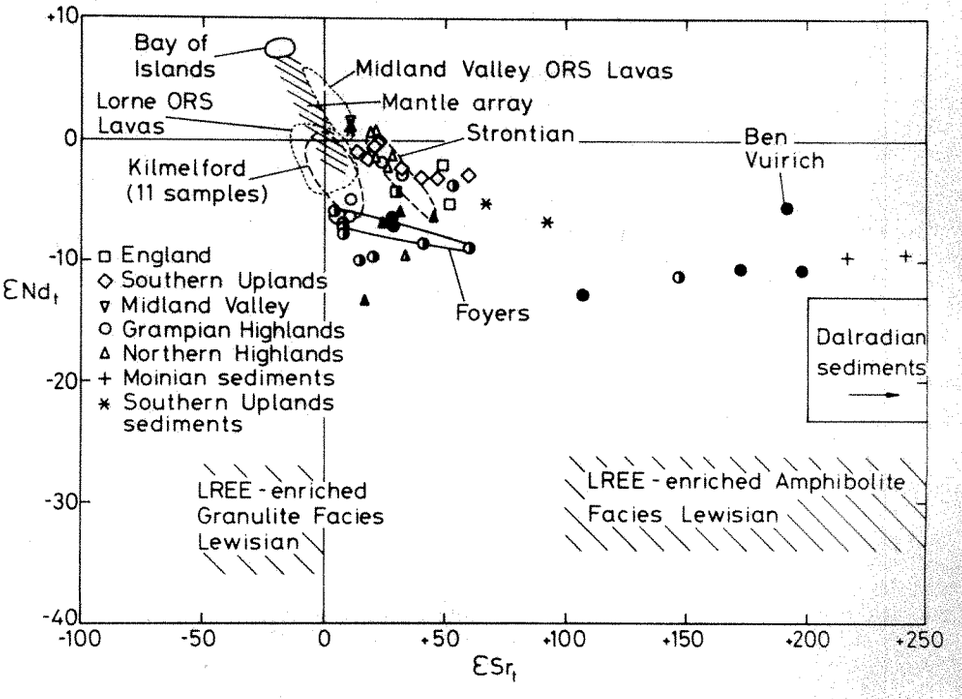

Fig. 3 ε_{Nd_t} versus ε_{Sr_t} plot showing data from the study of Hamilton *et al.*[4] and this study. Open symbols are for intrusions lacking inherited zircons, filled symbols are for intrusions with a marked inherited zircon memory, half-filled symbols are for intrusions with no U–Pb zircon data. Mantle array is constructed using bulk Earth parameters, the Bay of Islands ophiolite data[40] and by analogy with the modern mantle array. Other data sources are: Lewisian (ref. 28), Kilmelford (unpublished data), ORS Lavas (ref. 23), Moinian (ref. 25), Dalradian (ref. 8, 26).

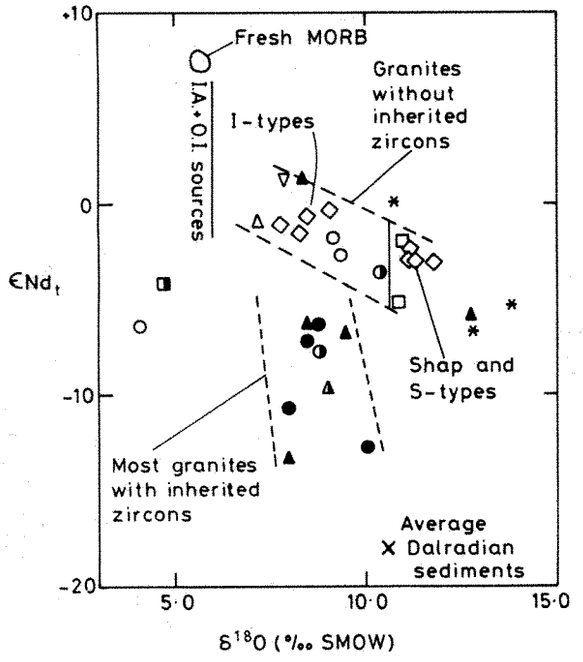

Fig. 4 ε_{Nd_t} versus $\delta^{18}O$. Symbols as in Fig. 3. Data from refs 4, 10, 11 and this study with estimates of fields for mid-ocean ridge basalts (MORB), oceanic islands (OI) and island arcs (IA). Dalradian average is from refs 26, 29.

metamorphism and diagenesis do not readily result in disturbance of U–Pb zircon or Sm–Nd systematics, hence the strong correspondence between those two parameters shown in Fig. 2, but the lack of strong correlation between ε_{Nd} and $\delta^{18}O$ or ε_{Sr} in the Highland granites (Figs 3 and 4).

The fundamentally important feature of Fig. 4 is that it indicates that granites with marked inherited zircon components and low ε_{Nd} have not been more contaminated by the continental crust than granites lacking inherited zircons and with $\varepsilon_{Nd} > -6$. They have instead been contaminated by or melted from a different kind of crust, that is, one with markedly older components.

Following on from this it can be seen that the Lochnagar, Hill of Fare and Garabal Hill granitoids, despite having high ε_{Nd} and no inherited zircons, have interacted to a major degree with continental crust yielding $\delta^{18}O$ values of ~10‰. Hence although situated in the Scottish Highlands their lack of inherited zircons and high ε_{Nd} do not reflect uncontaminated mantle-derived magmas, but magmas contaminated with young continental crust like that with which the Southern Uplands and English granitoids interacted. U–Pb zircon and Sm–Nd studies of Dalradian[8,26] lithologies indicate that melting of Dalradian crust would have lowered the ε_{Nd} drastically and imparted inherited zircons to the magma (Fig. 4). The data are therefore most simply explained if younger continental crust has been thrust under the southern side of the Grampian Highlands and provided the source for these granite magmas. Finally it should be noted that magmas with a large mantle component could easily plot in the area of intersection of the two fields in Fig. 4 whatever the contaminating crust was like.

Magma genesis in northern Britain

The British late Caledonian granites were clearly not generated by melting of mantle or subducted oceanic crust on their own. The combined data indicate that the continental crust has drastically affected the isotopic characteristics of the magmas. There are certain features of the magmas, however, which indicate that the granites are not simply the product of crustal melting but that many contain a mantle-derived component. These include the abundance of cogenetic high Ni dioritic magmas, the high levels of elements such as Sr (most easily achieved by differentiation at mantle depths) and the presence of cogenetic basaltic and andesitic lavas[27]. This, plus the large variation in ε_{Nd} observed in a single complex, such as at Kilmelford, suggests that in some cases mantle-derived magmas have assimilated continental crustal melts during their ascent.

In Fig. 3 the fields of data for Devonian mafic lavas from the Midland Valley and Lorne[23] are plotted. The Lorne Lavas are situated in the south-west Grampian Highlands (Fig. 1) and are thought to be cogenetic with the Kilmelford complex. Note that there is an overall downwards displacement of the plutonic data relative to the volcanics. This partly reflects the fact that the data for the volcanics are for high Ni lavas only, whereas the plutonics are largely granodiorites or granites. *Hence the more* silicic compositions can be (not surprisingly) related to greater interaction with the continental crust. Just as the granites south of the Mid-Grampian Line have higher ε_{Nd} than those to the north so also do the Devonian mafic volcanics but displaced overall to higher values (Fig. 3). This parallel behaviour is not regarded as coincidental but is most simply explained by the same process, that is, assimilation of differing ages of crust north and south of the Mid-Grampian Line. This alternative explanation is totally at variance with the mantle heterogeneity model previously invoked to explain the Nd data for the lavas[23].

The data for the lavas do indicate that magmas with 'depleted mantle' isotopic signatures were intruding the continental crust at the time. There is no way that one can assume that the same such magmas were parental to all the intermediate-acid magmatism in the Highlands. It would not be surprising, for example, if the changes in age of continental basement corresponded to changes in the nature of the underlying mantle. What is surprising is that even the diorites from Loch Doon with quite low $\delta^{18}O$ (Fig. 4) have negative ε_{Nd}. Unlike those of the Midland Valley these magmas yield no evidence of having been derived from depleted mantle or oceanic crust, which suggests that the Iapetus oceanic crust had been completely consumed by subduction under the Midland Valley by late Silurian times. This is contrary to previous suggestions[34]. It further requires that the crust underlying the Southern Uplands accretionary prism is allochthenous as suggested elsewhere[35,36].

Contamination with older continental crust might explain why the ε_{Nd} values of the British granites appear to be displaced by three units relative to the Australian granites. The contaminant clearly varies from Lewisian crust in the far north-west of Scotland to Lower Palaeozoic sediment in the Southern Uplands and Lake District. The exact nature of the basement in between is uncertain. Some of the northerly basement would need to be Lewisian or its sedimentary/magmatic derivatives (Moinian or Dalradian, for example) to produce low ε_{Nd} and marked inherited zircons. The southerly basement would need to be like Palaeozoic upper crust further south. Nd and U–Pb zircon data for granulite facies nodules erupted with Midland Valley Carboniferous Lavas indicate a striking similarity with corresponding data for Lower Palaeozoic sediments of the Southern Uplands[25,37]. A simple way to explain the data for the granites and the granulite facies basement is for the basement to represent Lower Palaeozoic crust thrust northward during Iapetus closure. The view that primary crust of Grenville (~1,000 Myr) age is an important crustal component in the Highlands granites[38] is difficult to reconcile with the U–Pb zircon evidence. In particular, nearly all of the late Caledonian granites analysed which contain inherited zircons yield data which lie about a reverse discordia with an upper intercept of ~1,600 Myr (ref. 6). Furthermore neither U–Pb zircon[8] nor Sm–Nd whole rock[26] studies of Scottish Highlands sediments provide evidence for local Grenville-age primary crust. Underthrusting of the crust during the late Caledonian helps to explain the problem of finding a unique crustal component in the Highlands granites[8,10,29,38] as the crustal structure is likely to have been exceedingly complex. It also provides a partial explanation for the large crustal component in the granites as a whole as juxtaposing crust over hot mantle would be a way of generating granite magma. The simplest interpretation of the data shown

in Fig. 4 is that the southerly crust was largely young accreted material such as arc, trench and oceanic crust fragments.

W. E. Stephens, M. Thirlwall, J. Soper, D. Hutton, B. J. Bluck and B. G. Upton have provided samples and discussion which have benefited the paper. I thank J. Hutchinson for technical assistance. J. Bennet, D. Maclean and J. Hewitt helped prepare the script. The Isotope Geology Unit at SURRC is supported jointly by the Scottish Universities and NERC. Research on the British Caledonian granites is also supported by the NERC grant GR3/4633.

Molecular cloning of cDNA for murine interleukin-3

M. C. Fung, A. J. Hapel,* S. Ymer, D. R. Cohen, R. M. Johnson, H. D. Campbell & I. G. Young

Departments of Biochemistry and *Medicine and Clinical Science, John Curtin School of Medical Research, Australian National University, PO Box 334, Canberra, ACT 2601, Australia

The cDNA sequence for murine interleukin-3, one of the colony stimulating factors that regulate haematopoiesis, codes for a polypeptide of 166 amino acids including a putative signal peptide. The predicted amino acid sequence indicates that formation of mature interleukin-3 involves proteolytic removal of not only the signal peptide but additional amino-terminal amino acids.

INTERLEUKIN-3 (IL-3) is one of a number of colony stimulating factors which are known to regulate haematopoiesis[1–3]. The colony stimulating factors are hormone-like glycoproteins which are biologically active at concentrations of 10^{-12} M. They are produced in minute quantities *in vivo* and because of this have proven to be very difficult to characterize by conventional biochemical methods.

IL-3 is produced by mitogen or antigen-activated T lymphocytes and by a number of continuous cell lines[4,5]. It may also be produced by bone marrow cells. IL-3 is involved in regulating the growth and differentiation of pluripotent stem cells leading to the production of all the major blood cell types. It has a broad range of biological activities and appears to be identical with a number of other factors named on the basis of their biological activities. These include multi-colony stimulating factor CSF, haematopoietic growth factor[6], burst-promoting activity[7], P-cell stimulating factor[8], mast cell growth factor[9], histamine-producing cell stimulating factor[10] and Thy 1-inducing activity[11].

Murine IL-3 derived from the myelomonocytic leukaemia cell line WEHI-3 has recently been purified to homogeneity and a portion of its N-terminal sequence and some of its biochemical and biological properties reported[12,13]. The protein is glycosylated and the molecular weight (MW) of the major glycosylated species was estimated to be 28,000. A second species of IL-3 with the same N-terminus was also purified which had an apparent MW of 32,500 suggesting that the two forms may differ in their degree of glycosylation. In the present work we describe translation of IL-3 mRNA in *Xenopus laevis* oocytes and the cloning and sequence analysis of a cDNA coding for murine IL-3.

Translation of IL-3 mRNA in oocytes

Two different murine cell lines were compared as sources of IL-3 mRNA. The myelomonocytic line WEHI-3 is known to produce IL-3 constitutively[14] whereas the lymphoma line EL-4 produces IL-3 after stimulation with phorbol myristate acetate (PMA)[5]. Messenger RNA was prepared from both cell lines using the guanidine thiocyanate method[15,16]and attempts were made to translate the mRNAs by microinjection into *X. laevis* oocytes[17]. The translates were assayed for biologically active IL-3 using the IL-3 dependent cell line 32D cl-23 (ref. 18). It was found that mRNA from EL-4 could be translated in the oocytes to give readily detectable levels of IL-3 after 48 h incubation (Table 1). Most of the detectable activity was present in the incubation medium indicating that the oocytes were secreting mature IL-3. Assays of oocyte extracts showed that they were inhibitory. mRNA from WEHI-3 cells regularly gave higher levels of IL-3 in the translation assays than preparations from EL-4 (Table 1), in keeping with the higher levels of IL-3

© 1984 Macmillan Journals Ltd

Table 1 Translation of IL-3 mRNA in *Xenopus laevis* oocytes

mRNA	Incubation time	IL-3 activity (c.p.m.) Oocyte	Medium	Total extract
EL-4	24 h	0	3,100	3,700
	48 h	—	20,000	5,600
WEHI-3	48 h	6,000	47,000	28,700

EL-4 cells were grown to a cell density of $\sim 10^6$ per ml in spinner cultures in DMEM medium supplemented with 10% fetal calf serum. The cells were collected by centrifugation, resuspended in serum-free medium containing 100 ng ml^{-1} PMA and subcultured into 150 cm^2 culture flasks at 5×10^8 cells per flask. The cells were incubated for 10 h before collection. WEHI-3 cells were grown to a density of $\sim 10^6$ per ml in RPMI-1640 medium supplemented with 10% fetal calf serum and collected by centrifugation. Afterwards, both cell pellets were resuspended in 0.1 volume of serum-free medium and mRNA was prepared by the guanidine thiocyanate-CsCl method[15,16]. The mRNAs were further purified by chromatography on oligo(dT)-cellulose[32] and after ethanol precipitation, were resuspended in buffer (10 mM Tris-HCl, 0.1 mM EDTA, *p*H 7.5) at a concentration of 1 μg μl^{-1}. The mRNAs were injected into 15 *X. laevis* oocytes (~50 nl per oocyte) according to standard methods[17]. After incubation, the medium was withdrawn and an extract of the oocytes prepared[17]. The incubation medium, the oocyte extract and a mixture of the two were assayed for IL-3 activity using the IL-3 dependent cell line 32D cl-23 (ref. 18) according to the methods described previously, measuring incorporation of ^{3}H-thymidine as an index of cell growth.

Table 2 mRNA hybridization translation assay for detection of IL-3 cDNA clones

10	<1

DNA samples (~30 μg) were prepared from each clone by the method of Holmes and Quigley[21]. The hybrid plasmid DNA was converted to a linear form by digestion with *Bam*HI restriction endonuclease, extracted with phenol and ethanol precipitated. The DNA was heated in 0.1 M NaOH for 20 min at 70° C, diluted with 20 vol of 2 M NaCl and applied to 1 cm diameter nitrocellulose filters by slow filtration. The filters were washed with 6×SSC (1×SSC: 0.15 M NaCl, 0.015 M Na citrate, *p*H 7.0) and baked *in vacuo* at 80 °C for 2 h. The 10 membranes were hybridized with 400 μg WEHI-3 mRNA under the conditions described previously[31] and the bound mRNA eluted according to the procedure of Parnes *et al.*[33]. The eluted mRNA was translated in oocytes as described in Table 1. A unit of IL-3 activity is that required to give 50% of the maximum incorporation of ^{3}H-thymidine in the assay.

found in culture supernatants of the WEHI-3 cell line (data not shown).

Hybrid plasmids containing IL-3 cDNA

IL-3 mRNA from WEHI-3 was fractionated on a sucrose density gradient and the fractions assayed by oocyte translation (Fig. 1). The major peak of activity sedimented at ~12S. This procedure resulted in 10–20-fold purification of the IL-3 mRNA. RNA from the peak fractions was used as template to synthesize double-stranded cDNA using the method of Land *et al.*[19]. The resultant cDNA was inserted into pAT153 by G–C tailing[20] and the cDNA library transformed into strain HB101. Approximately 5,000 individual clones were isolated. Of a small sample tested, 92% were ampicillin sensitive indicating the presence of cDNA inserts in the majority of the clones. Since the cDNA was not size fractionated prior to cloning, the sizes of inserts in the cDNA library varied from about 200 to 1,000 base pairs (bp). It was expected that even the short inserts would give satisfactory results in the mRNA hybridization–translation assay (see below).

Clones were grown in pools of 10 and DNA prepared by the method of Holmes and Quigley[21]. The plasmids were converted to a linear form with *Bam*HI restriction endonuclease, contaminating RNA was destroyed by alkaline hydrolysis and the DNA was bound to nitrocellulose filters. The filter-bound DNA was hybridized with WEHI-3 mRNA and bound mRNA eluted and translated in oocytes. One positive pool of 10 clones was detected. The activity observed in translates derived from the positive pool was quite low but was consistently above the background and the values of the other clone pools. DNA was therefore prepared from the individual clones of the pool and the mRNA hybridization translation assay repeated. One of the clones (pILM1) was clearly positive (Table 2). The IL-3 activity detected showed the same titration curve as oocyte translates of WEHI-3 mRNA (Fig. 2).

Nucleotide sequence analysis

The cDNA insert in pILM1 was quite short (139 bp excluding the G-C tails). It was subcloned into the *Sma*I site of M13mp8[22] after shortening the G-C tails with *Bal*31 exonuclease. The DNA sequence was determined on both strands using the chain termination method[23,24]. An oligonucleotide primer corresponding to nucleotides 92–112 of this cDNA insert was synthesized[25,26] and labelled using [γ-^{32}P]dATP and polynucleotide kinase[27]. The labelled probe was used to examine the remaining clones in the cDNA library[28,29]. No other clones containing this sequence were detected.

To isolate a long clone encoding IL-3, a further cDNA library was prepared, but in this case the double-stranded cDNA was size fractionated using Sepharose CL-4B to enrich for cDNA fragments larger than ~500 bp. The resulting cDNA was inserted into pAT153 by G-C tailing and transformed into HB101. The labelled oligonucleotide probe described above was used to identify a longer cDNA clone (pILM3) which was shown by DNA sequencing to carry an insert of 629 bp excluding the G-C tails. The DNA sequence of clone pILM3 was determined on both strands using the chain termination method[23,24] after subcloning into M13mp8 and 9 (ref. 22). The sequencing strategy is given in Fig. 3*a*. The subcloning was complicated by the fact that one of the *Pst*I sites flanking the cDNA insert had been lost due to exonucleolytic removal of one nucleotide during the G tailing of the vector. Clone pILM3 was found to extend beyond pILM1 at the 3′ end only, both clones possessing the same 5′ end. The DNA sequence shows a single large open reading frame (Fig. 3*b*). Assuming that the first ATG from the 5′ end serves as the initiation codon, the reading frame extends from nucleotides 28–525 inclusive and specifies a polypeptide of 166 amino acids. The 5′ untranslated region is therefore quite short (27 bp). The method of Land *et al.*[19], which was used to generate the cDNA clones, is designed to produce a high proportion of cDNA clones with complete 5′ terminii. Since both cDNA clones isolated in the course of this work had the same 5′ end, it is possible that pILM3 carries a close to full length copy of the 5′ untranslated region of IL-3 mRNA. Clone pILM3, however, does not extend to the 3′ end of the IL-3 mRNA and is probably missing a significant portion of the 3′ untranslated region. The presence of the complete coding sequence for IL-3 is the important feature in the context of the present work.

The reading frame specifies a protein of MW 18,540. The strongly hydrophobic stretch of 9 amino acids (residues 13–21) is indicative of the presence of a signal peptide. In the cases studied to date, the last residue of the signal sequence is invariably an amino acid with a small uncharged side chain. Analysis of the signal peptide region suggests a number of potential sites for cleavage by the signal peptidase. Application of the empirical rules proposed by Von Heijne[30] predicts the end of the signal peptide at residue 27 (Ala). This potential cleavage site is shown with an arrow in Fig. 3*b*.

Table 3 Amino acid composition of murine IL-3

	Predicted	Determined
Phe	5	4.2
Leu	15	16.7
Ile	5	4.8
Met	1	1.2
Val	10	8.3
Ser	13	11.3
Pro	10	7.1
Thr	8	7.1
Ala	3	4.2
Tyr	2	1.8
His	2	2.4
Glu, Gln	12	13.7
Asp, Asn	18	16.1
Lys	9	9.5
Cys	4	ND
Trp	0	ND
Arg	11	9.5
Gly	6	8.3

The amino acid composition data are taken from ref. 13. The composition was originally calculated for a MW of 23,722 and has been normalized to the size of mature IL-3 which is predicted from the DNA sequence. The normalization was done using the values for Glu and Asp. ND, not determined.

The published N-terminal amino acid sequence of murine IL-3[12,13] is in complete agreement with the reading frame and extends from residues 33 (Asp) to 47 (Val). It seems most unlikely that the signal peptide would end at residue 32 (Arg) and this suggests that the murine IL-3 isolated from the WEHI-3 cell line has been further processed.

The protein sequence of mature processed IL-3 indicates a MW of 15,102 with four potential *N*-glycosylation sites (Asn-X-Ser or Asn-X-Thr). The four sites are underlined in Fig. 3*b*. One of these is in the region of the published N-terminal sequence and glycosylation at this site would explain the inability to identify the Asn residue during automated Edman degradation. When the amino acid composition figures for murine IL-3 (ref. 13) are normalized to the size predicted by the DNA sequence they give good agreement with the predicted composition (Table 3).

The amino acid sequence of murine IL-3 was compared with the sequences of human interleukin-2 (ref. 31) and human immune interferon[32] both of which are also produced by antigen-activated T lymphocytes. No significant sequence homology was detected. Although human IL-2 is of very similar size to IL-3 it carries no potential sites for *N*-glycosylation and does not appear closely related.

Discussion

The demonstration that IL-3 mRNA can be efficiently translated in oocytes to give biologically active factor provides a very sensitive and useful assay for this mRNA. This assay has enabled the identification of a cDNA clone carrying the entire coding sequence for murine IL-3 using the mRNA hybridization translation method.

Sequence analysis of the cloned cDNA has shown that it codes for a polypeptide of 166 amino acids including a signal peptide of possibly 27 amino acids. Mature IL-3 has been purified to homogeneity[12,13] from the same WEHI-3 cell line as was used as the source of the IL-3 mRNA in the present work. The N-terminal sequence of the mature IL-3 is in complete agreement with the reading frame but starts at residue 33 suggesting an additional proteolytic cleavage has occurred apart from the cleavage of the signal peptide. The proposed proteolytic cleavage could be catalysed by a number of serine-type proteases such as a member of the kallikrein family or plasmin and could provide another level of regulation if processing was required to generate biologically active IL-3. Whether this processing

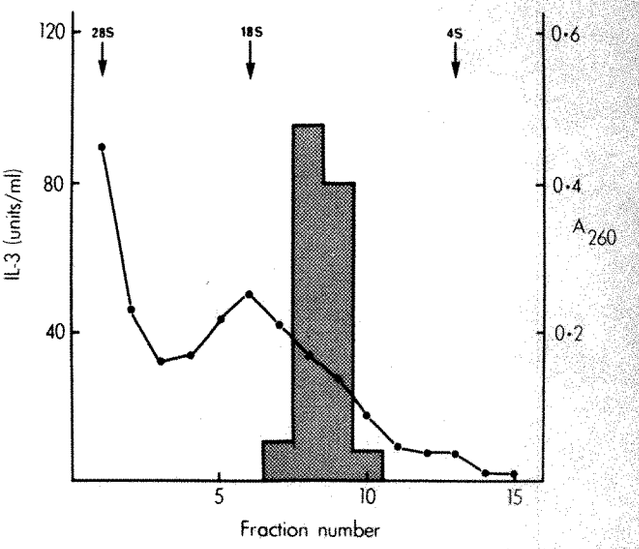

Fig. 1 Sedimentation of IL-3 mRNA through a sucrose density gradient. ●, A_{260}; hatched areas, IL-3 activity. Poly(A)$^+$ mRNA (500 μg) from WEHI-3 was heated at 80° C for 2 min, chilled in ice and applied to a 5–20% sucrose gradient prepared in a Beckman SW41 polyallomer tube. The gradient was centrifuged at 30,000 r.p.m. for 20 h at 4 °C and fractionated into 15 fractions by collection of drops. The fractions were ethanol precipitated and resuspended in 20 μl of buffer (10 mM Tris HCl, 0.1 mM EDTA, *p*H 7.5). A portion of the RNA was electrophoresed on a 1.5% agarose gel. The RNA was also translated in *X. laevis* oocytes as described in Table 1. One unit of IL-3 activity is that required to give 50% of the maximum incorporation of ^{3}H-thymidine in the assay.

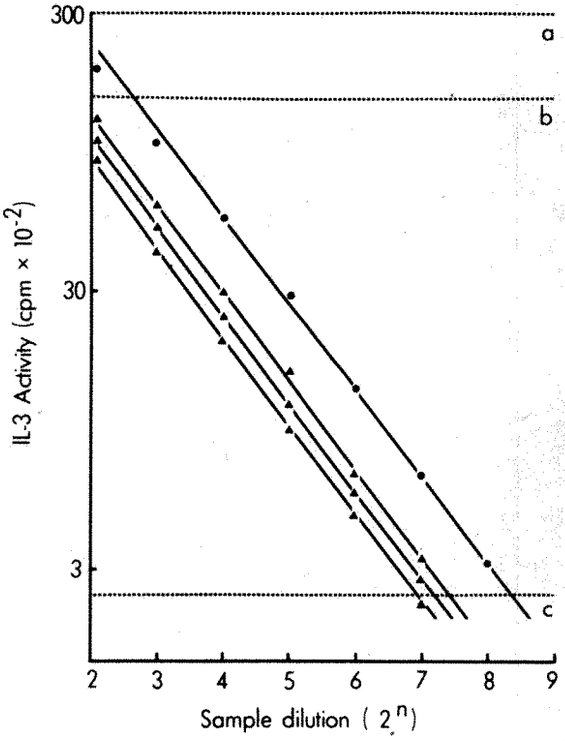

Fig. 2 Titration curves for the IL-3 activity present in oocyte translates. △, Translates of mRNA hybridizing to pILM1 (see Table 2); ●, translates of WEHI-3 mRNA. Twofold dilutions of the oocyte translates were made in microtitre trays and the IL-3 activity present was measured using the IL-3 dependent cell line 32D cl-23 as described previously[18]. The stimulation of growth of the indicator cells is expressed in terms of ^{3}H-thymidine incorporation. The dotted lines designated a, b and c represent incorporations of 100%, 50% and background plus three standard deviations respectively.

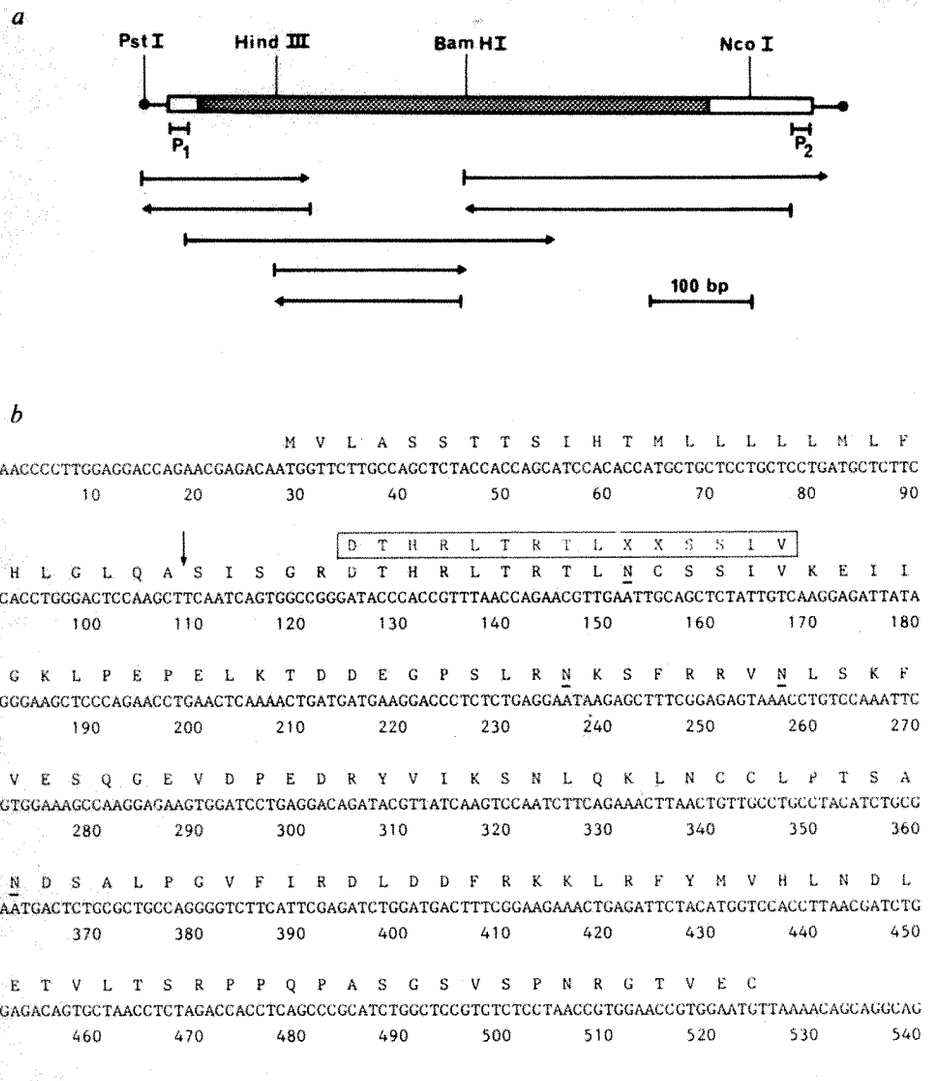

Fig. 3 *a*, The cDNA insert in pILM3 showing the relevant sites of restriction endonuclease cleavage. The reading frame is delineated from the untranslated regions by hatching and the flanking G-C tails are shown as short bars. One of the expected *Pst*I sites was lost during G-tailing of the vector pAT153. The sequencing strategy is summarized beneath the cDNA insert. DNA sequencing was carried out by the chain termination method[23,24] after subcloning fragments of pILM3 into M13mp8 and M13mp9[22]. The computer programs described by Staden[34,35] were used to assemble and analyse the sequence data. To avoid interference from the longer G-C tails, which was encountered using the universal primer of Duckworth *et al.*[36], two internal primers (P_1 and P_2) 17 nucleotides in length were synthesized[25,26] and used with the M13 templates. *b*, Nucleotide sequence of the cDNA insert of pILM-3 and predicted amino acid sequence of murine IL-3. The N-terminal sequence of murine IL-3[12,13] is boxed in above the predicted amino acid sequence. Potential sites for *N*-glycosylation are underlined. The arrow indicates a possible site of cleavage for removal of the signal peptide[30].

step occurs *in vivo* or simply represents adventitious proteolysis during purification is not clear at present.

Apart from the agreement with the N-terminal sequence, the amino acid composition data for mature IL-3 also give good agreement with the predicted sequence. Since it appears that WEHI-3 only produces one member of the group of colony stimulating factors (that is, IL-3), there seems no doubt that the cDNA clone encodes IL-3.

The isolation of a cDNA clone encoding murine IL-3 opens up a number of new molecular approaches to studying the role of this factor in haematopoietic stem cell differentiation. It should prove valuable in studies of proliferative blood disorders such as certain leukaemias and polycythaemias and should enable adequate quantities of murine IL-3 to be produced using suitable expression systems. It should also facilitate isolation of cDNA clones for human IL-3 and allow investigation of potential applications of this factor in clinical medicine in the area of bone marrow transplantation following cancer chemotherapy.

We thank Drs W. Doe and K. Lafferty for discussions, Drs D. Curtis and J. Shelton for assistance with the microinjection methods, Mr G. Mayo, Dr D. Magrath and Dr W. Amarego for their help with the synthesis of oligonucleotides and Ms J. Byatt and Ms J. Osborne for technical assistance.

Note added in proof: The CDNA encoding IL-3 has now been expressed in monkey COS cells using an SV40 expression vector. The expressed factor supports the growth of the IL-3 dependent cell lines; its full range of biological activities is currently being tested in collaboration with Dr D. Metcalf, Walter and Eliza Hall Institute of Medical Research, Melbourne.

A molecular map of the human major histocompatibility complex class III region linking complement genes C4, C2 and factor B

Michael C. Carroll, R. Duncan Campbell, David R. Bentley & Rodney R. Porter

MRC Immunochemistry Unit, Biochemistry Department, Oxford University, South Parks Road, Oxford OX1 3QU, UK

Four human complement genes, which have previously been mapped between HLA-D and HLA-B on chromosome 6, have now been aligned on a 98-kilobase (kb) section of the chromosome on the basis of four overlapping cosmid clones of genomic DNA. The C2 and factor B genes, less than 2 kb apart, are about 30 kb from two C4 genes separated from each other by about 10 kb.

THE major histocompatibility complex (MHC) in man (HLA) is a highly polymorphic region of approximately 2 centimorgans (2×10^6 base pairs, bp) on the short arm of chromosome 6[1]. It contains three major classes of genes: class I and class II code for cell-surface glycoproteins which are concerned in self–non-self recognition of cells involved in the immune response, and class III code for some proteins of complement, the major effector system of humoral immunity[2]. There is clinical interest in the HLA not only because the products of the class I and class II genes are the major barrier to tissue transplantation but also because susceptibility to many autoimmune diseases is correlated with the presence of certain haplotypes of class I and II[3] and also, because of close linkage[4], of the class III genes. It has been suggested that the polymorphism of the class III proteins may be a factor in susceptibility to autoimmunity[5].

The class III genes code for the complement proteins C2, C4 and factor B. C2 and factor B are novel types of serine proteases which, on activation in association with C4 and C3, respectively, form the C3 convertases of the classical pathway ($\overline{C42}$) and the alternative pathway ($\overline{C3B}$) of complement activation[6]. C2 and factor B are single peptide-chain proteins of approximately 100,000 and 90,000 molecular weight (M_r) while C4 has three disulphide-linked chains, α (95,000 M_r), β (75,000) and γ (30,000), but is synthesized as a single peptide chain of 200,000 M_r (ref. 7).

The structural genes of C4, C2 and factor B have been mapped between HLA-B and HLA-D using protein variants detected mainly by electrophoresis (summarized by Weitkamp and Lamm[8]). C2 and factor B seem to be encoded at single loci but C4 is coded by at least two closely linked loci, C4A and C4B (ref. 9). Four alleles have been recognized in C2 (ref. 10), 11 in factor B[11], 13 at C4A and 22 at C4B[12]. Null (non-functional) alleles have also been found in C2, C4A and C4B but not so far in factor B[8].

The recent availability of cDNA probes specific for factor B[13,14], C4[15–17] and C2[18] has allowed the isolation of these complement genes. The factor B gene has been isolated and characterized by extensive nucleotide sequence analysis[14]. The C4 cDNA probe has been used to characterize partially a C4 gene[15] and to correlate a DNA restriction fragment length polymorphism with the C4 A6 protein phenotype[19].

We have used cDNA probes specific for C4,[15] factor B[14] and C2[18] to map the genes for these three complement proteins in the HLA class III region, by overlapping cloned fragments from a cosmid library of human genomic DNA. The results were confirmed and extended by Southern analysis of whole genomic DNA. There are at least four class III genes in 98 kilobases (kb) of genomic DNA. There are two C4 loci separated by approximately 10 kb and single factor B and C2 loci which are less than 2 kb apart. The genes are arranged in the order C2, factor B and two C4 genes.

Detection of two C4 genes

The HPFH cosmid library (described in Fig. 2 legend) prepared from genomic DNA extracted from blood cells of a 13-yr-old female, complement typed as C4: A3, A2, B1, B2; factor B: SS; (C2 not determined), was screened with a C4-specific cDNA probe, *Alu-7* (ref. 15). Positive clones were identified and the DNA inserts characterized by restriction mapping. Two cosmid clones, 1E3 and 3A3, were shown together to contain a complete C4 coding sequence as determined by hybridization of Southern blots with a full-length cDNA probe, clone TB13 (probe H) (K. T. Belt, M.C.C. and R.R.P., unpublished). The approximate gene size is 21 kb; however, the exact position of the 5′ end of the gene has not been determined. The insert of clone 1E3 also contained 7.5 kb of the 5′ end of a second C4 gene approximately 10 kb downstream from the 3′ end of the *C4z* gene. These two genes have been labelled as *C4y* and *C4z* as it is not clear which gene represents the C4A and C4B loci.

A comparison by restriction mapping of the 5′ ends of the two C4 genes showed that they were similar but that the *C4y* gene was characterized by 3.3-kb *Bam*HI, 3.5-kb *Kpn*I and 12-kb *Bgl*II fragments, whereas the *C4z* gene had 4.6-kb *Bam*HI, 12-kb *Kpn*I and 14.5-kb *Bgl*II fragments in the homologous region.

Southern analysis of genomic DNA from a sample of 72 individuals (data not shown), including the donor (HPFH) for the genomic library, suggests these two different forms of C4 gene are common in the population. Figure 3 shows a southern blot of genomic DNA from the library donor digested with *Kpn*I, *Bam*HI, or both and hybridized with a 400-base pair

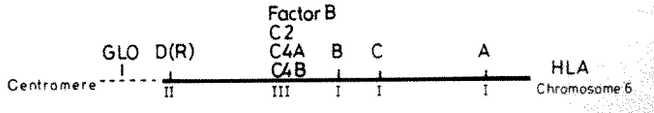

Fig. 1 Map of HLA region on the short arm of human chromosome 6 showing the approximate positions of the class I genes (A, B, C), the class II genes D(R) and the class III genes, factor B, C2, C4A and C4B. The glyoxalase gene (GLO) lies between D(R) and the centromere.

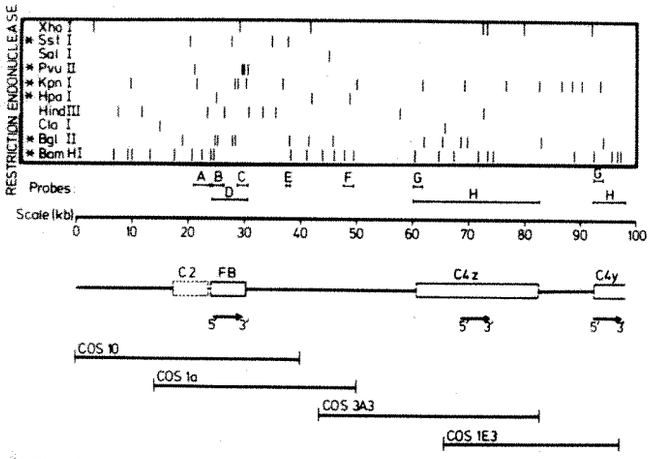

Fig. 2 Molecular map of 98 kb of genomic DNA in the HLA class III region containing four complement genes. Approximately 200,000 colonies from the HPFH cosmid library, prepared by F. Grosveld[26] from genomic DNA extracted from white blood cells of a 13-yr-old female, were screened with C4[15] and factor B[14] cDNA probes. DNA inserts from positive clones were characterized further by restriction mapping and Southern analysis using probes A–H as described below. Four cosmid clones 10, 1a, 3A3 and 1E3 were shown to overlap covering a total distance of 98 kb. Probes used: A, 400-bp C2 cDNA, pC201; B, 660 bp *ClaI*/*Bam*HI fragment from 5′ end of full-length factor B cDNA clone pFB3b; C, 500 bp *Xho*I/*Bam*HI fragment from 3′ end of full-length factor B cDNA clone pFB3b; D, 2.4-kb full-length factor B cDNA clone, pFB3b; E, 600-bp *Sst*I/*Bam*HI fragment from Cos 1a; F, 1.6-kb *Bam*HI fragment from Cos 3A3; G, 400-bp *Bam*HI/*Kpn*I fragment from 5′ end of full-length C4 cDNA clone TB13; H, 5.4-kb full-length C4 cDNA clone.
Methods: Colonies were plated onto 16 nitrocellulose filters (14 cm Millipore HAWP, 0.45 μM) on nutrient agar plates with ampicillin. Replicas were prepared and processed for colony hybridization according to Grosveld *et al.*[27]. Prehybridization and hybridization conditions, solutions and procedure for nick translation of probes are described in Fig. 3 legend. After hybridization, filters were washed with four changes of 0.3 M NaCl/0.03 M sodium citrate at room temperature, four changes of 0.15 M NaCl/0.015 M sodium citrate at 65 °C over 2 h and finally with two changes of 0.03 M NaCl/3 mM sodium citrate at 65 °C for 30 min each. Filters were dried and autoradiographed at −70 °C for 1–2 days. Cosmid DNA was extracted from bacterial colonies by using the alkaline SDS method[28] and the inserts characterized by single and double digestion with various restriction endonucleases using the manufacturer's specified conditions. Separation of restriction fragments by agarose gel electrophoresis and transfer to nitrocellulose filters for Southern analysis was performed as described in Fig. 3 legend. Positioning of the four genes was based on hybridization with the respective cDNA probes. As the probes (all but E and F) were for coding sequence, the precise limits of the genes were only defined for the 3′ end of the factor B gene[14]. Orientation of gene transcription for factor B, *C4z* and *C4y* was determined by hybridization with cDNA probes specific for 5′ and 3′ ends.

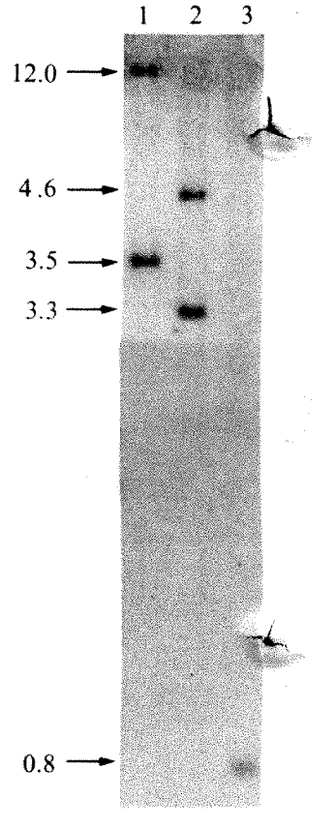

Fig. 3 Two common forms of C4 gene in genomic DNA. Southern[29] analysis of *Kpn*I (track 1), *Bam*HI (track 2) or *Kpn*I/*Bam*HI (track 3) digests of genomic DNA from individual HPFH hybridized with a 400-bp cDNA probe G, specific for 5′ coding sequence of a full-length cDNA TB13, probe H (see Fig. 2 for position of probes). The 3.3-kb *Bam*HI and 3.5-kb *Kpn*I bands are characteristic of *C4y*, whereas the 4.6-kb *Bam*HI and 12-kb *Kpn*I bands are characteristic of the *C4z* gene. The single 0.8-kb *Kpn*I/*Bam*HI band in track 3 is common to both *C4y* and *C4z* genes.
Methods: Genomic DNA was prepared from whole blood by the procedure of B. Sykes (unpublished). Briefly, after lysis of cells in 0.9% NaCl/0.1% Nonidet P40, pellets were broken up in lysis buffer (7 M urea, 0.3 M NaCl, 10 mM EDTA, 10 mM Tris-HCl *p*H 7.5) with a glass rod, and incubated at 37 °C for 10 min after the addition of 2% SDS. DNA was extracted 3× with phenol/isoamyl alcohol/chloroform (45:10:45) followed by precipitation by ethanol and dialysis against 10 mM Tris-HCl *p*H 7.5, 1 mM EDTA. For Southern analysis, 8–10 μg DNA samples were digested for 20 h at 37 °C in a final volume of 50 μl with 18 U of the respective restriction endonuclease according to the manufacturer's specifications (Boehringer Mannheim), electrophoresed in 0.8% agarose and transferred to nitrocellulose filters (Sartorius). Nitrocellulose filters were prehybridized at 42 °C for at least 2 h in 50% formamide, 1 M NaCl, 0.01 M EDTA, 10 × Denhardt's solution, 10% dextran sulphate, 50 mM Tris-HCl *p*H 7.5, 0.1% sodium pyrophosphate and 0.1 mg ml^{-1} of heat-denatured herring sperm DNA[30] and then hybridized with nick-translated (Amersham International)[31], heat-denatured DNA probes with a specific activity of 10^8 c.p.m. μg^{-1} (0.5 μCi ml^{-1}) for 24–48 h. After hybridization, filters were washed six times for 10 min in 2 × SSC, 0.1% SDS (1 × SSC = 0.15 M NaCl, 0.015 Na citrate) and six times for 10 min at 68 °C in 1 × SSC, 0.1% SDS. After drying, filters were exposed to X-ray film with an intensifying screen at −70 °C for 2 days. Sizes of all bands were estimated on the basis of radioactive size markers (not shown).

(bp) C4 cDNA probe, G, a *Bam*HI/*Kpn*I fragment from the 5′ end of full-length cDNA clone TB13 (probe H). Both forms of the C4 gene are seen as characterized by 3.3-kb *Bam*HI and 3.5-kb *Kpn*I for *C4y* and 4.6-kb *Bam*HI and 12-kb *Kpn*I bands for *C4z*. Only a single hybridizing band of 0.8 kb is seen after double digestion with *Kpn*I and *Bam*HI, suggesting that the two genes are similar in this region. It is not known if these restriction site differences are representative of coding sequence differences.

Preliminary characterization of a third cosmid clone which possibly overlaps clone 1E3 but not 3A3 (data not shown) suggests that a third C4 gene may be present and this is being investigated further (M.C.C., unpublished observation).

A single factor B gene

Initial screening of 200,000 clones of the HPFH cosmid library using the 515-bp factor B-specific cDNA probe, FBI[14], resulted in the isolation of one positive clone (cos 1a) with an insert of approximately 35 kb. To generate overlapping clones and extend the region of DNA, a 600-bp *Bam*HI/*Sst*I fragment, probe E (Fig. 2), lying 12 kb from the 3′ end of cos 1a was used as a hybridization probe of the library. A further six positive clones were isolated and characterized. Four appeared to be identical with cos 1a, while two (cos 10 and cos 16) extended cos 1a by 14 kb at the 5′ end (Fig. 2).

Extensive mapping and Southern blot analysis of the cloned genomic DNA using a 2.4-kb full-length cDNA probe, D (ref. 20), showed the presence of only one factor B gene within this region (Fig. 2). The probe hybridized to adjacent 2.7- and 4.4-kb *Hin*dIII fragments, and sequence analysis[14] has shown that the 3′ end of the gene lies approximately 150 bp from the 3′ end of the 4.4-kb fragment (Fig. 2). The 5′ end of the gene was mapped using an 81-bp cDNA probe, generated from the full-length clone by a *Bam*HI/*Sau*3A double digest[20]. The probe, which contained coding information for 9 amino acids at the N-terminus of Ba and 10 amino acids of a putative leader peptide, hybridized to a 600-bp *Bam*HI fragment contained within the 2.7-kb *Hin*dIII fragment (Fig. 2). The 3′ end of the *Bam*HI fragment was shown by sequence analysis to encode the N-terminus of Ba and four amino acids of the leader peptide, before running into an intron. Thus, the region that codes for the mature factor B protein is contained within 5.7 kb of DNA.

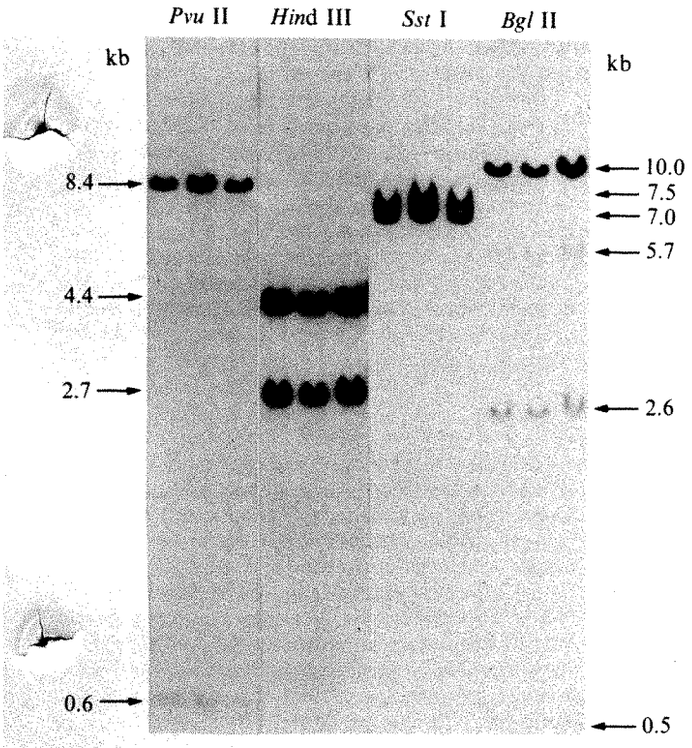

Fig. 4 Southern blot analysis of genomic DNA from three unrelated individuals with the 2.4-kb factor B cDNA probe, pFB3b. 10 μg of DNA was digested to completion with the enzyme indicated, separated on a 0.7% agarose gel and transferred to nitrocellulose filters as described in Fig. 3 legend. The insert of clone pFB3b, probe D (see Fig. 2), was excised using a *Cla*I/*Bam*HI double digest, and the 660-bp and 1.6-kb fragments generated were purified by elution from a polyacrylamide gel. The fragments were mixed in equal ratio and nick translated to a specific activity of $0.4–1 \times 10^8$ c.p.m. per μg DNA such that the hybridization mix contained $\sim 5 \times 10^5$ c.p.m. per ml. Conditions for hybridization, washing and autoradiography were as described in Fig. 3. Unequal intensity of 10-kb and 2.6-kb *Bgl*II fragments is due to unequal labelling of the mixed probes on nick translation.

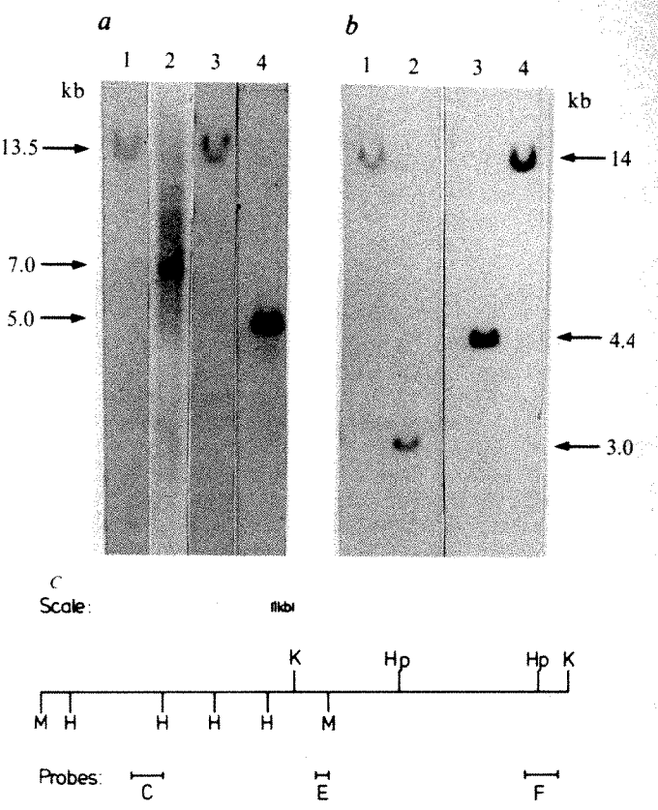

Fig. 5 Genomic probes from cosmid clones containing C4 and factor B genes hybridize to a common genomic restriction fragment. ***a***, Genomic DNA was digested with restriction endonuclease *Kpn*I only (tracks 1, 3) or both *Kpn*I and *Hpa*I (tracks 2, 4) and analysed on Southern blots as described in Fig. 3 legend. After hybridizing first with probe F (tracks 1, 2) from cos 3A3 (containing the C4 gene), the filter was treated with 0.5 M NaOH to remove the first probe, neutralized and prehybridized as described in Fig. 3 legend, then hybridized with probe E (tracks 3, 4) from cos 1a (containing the factor B gene). The 13.5-kb *Kpn*I fragment in tracks 1 and 3 hybridized with both genomic probes. After double digestion with *Kpn*I and *Hpa*I shown in tracks 2 and 4, the 13.5-kb *Kpn*I fragment is split into 7- and 5-kb fragments which hybridize with probes F and E, respectively. The 1.5-kb *Kpn*I/*Hpa*I fragment is not seen, because fragments of that size electrophoresed off the gel. For illustration, tracks 1 and 3 from one filter were combined with tracks 2 and 4 from a second filter. ***b***, Genomic DNA was digested with *Bam*HI (tracks 1, 4) or both *Bam*HI and *Hin*dIII (tracks 2, 3) and analysed on Southern blots (see Fig. 3 legend). Samples 1 and 2 were hybridized with genomic probe E from cos 1a while samples 3 and 4 were hybridized with the cDNA probe C (see Fig. 2 legend). Both probes hybridized to a common 14-kb *Bam*HI fragment (tracks 1, 4). After double digestion with *Bam*HI and *Hin*dIII, probe E hybridized to a 3-kb fragment (track 2) while probe C hybridized to a 4.4-kb fragment (track 3) as predicted from the map in Fig. 2. ***c***, Line diagram of restriction map covering region of overlap between cos 3A3 and Ia and factor B gene. Restriction enzymes used: K, *Kpn*I; Hp, *Hpa*I; M, *Bam*HI; H, *Hin*dIII.

Due to the close linkage of the factor B and C2 genes (see below), it is likely that the regions responsible for the control of factor B expression lie within the 600-bp *Bam*HI fragment, suggesting that the complete gene is about 6 kb long.

Southern blot analysis of various digests of genomic DNA from three unrelated individuals (Fig. 4) showed that in all cases the sizes of the restriction fragments hybridizing to the factor B probe (D) were as predicted from the map in Fig. 2. The results of these and other digests (*Kpn*I, *Bam*HI, *Acc*I, *Eco*RI, data not shown) indicate the presence of a single factor B gene per chromosome.

The C4 and factor B genes are linked

DNA inserts from cosmid clones 3A3 (containing the C4 gene) and 1a (containing the factor B gene) were shown to overlap by approximately 6 kb. Complementary sequence in this region was further proven by preparing a probe from clone 3A3 in the region of overlap. A 1.6-kb *Bam*HI genomic fragment (probe F, see Fig. 2) was nick translated and hybridized to a Southern blot comparing clones 3A3 and 1a. Probe F from clone 3A3 hybridized to the common restriction fragments in clone 1a, proving that the cloned inserts were complementary in the region of restriction site overlap.

To prove that these class III genes exist in the same order in uncloned genomic DNA, the two cosmid probes F and E (see Fig. 2) isolated from clones 3A3 and 1a, respectively, were hybridized to Southern blots of genomic DNA digested with either the single enzyme *Kpn*I or double digested with both *Kpn*I and *Hpa*I. As shown in Fig. 5*a*, both probes hybridized to the 13.5-kb *Kpn*I fragment. The double digest with *Kpn*I and *Hpa*I gave two fragments, a 7-kb band which hybridized only with probe F, and a 5-kb band which hybridized only with probe E. Second, the two probes E and C were hybridized to blots of genomic DNA digested with *Bam*HI only, or *Bam*HI and *Hin*dIII. Both hybridized to a common 14-kb *Bam*HI fragment (Fig. 5*b*, tracks 1, 4). When the DNA was digested with *Bam*HI and *Hin*dIII, probe E hybridized only to a 3-kb fragment while probe C hybridized to a 4.4-kb fragment. Linkage of genomic probe F with probe G, a C4 cDNA probe, was demonstrated by hybridizing to a common 14.5 *Bgl*II fragment (not shown). These results of Southern blots of genomic DNA confirmed the linkage of the *C4z* gene to the factor B gene proposed from the results of the cosmid mapping.

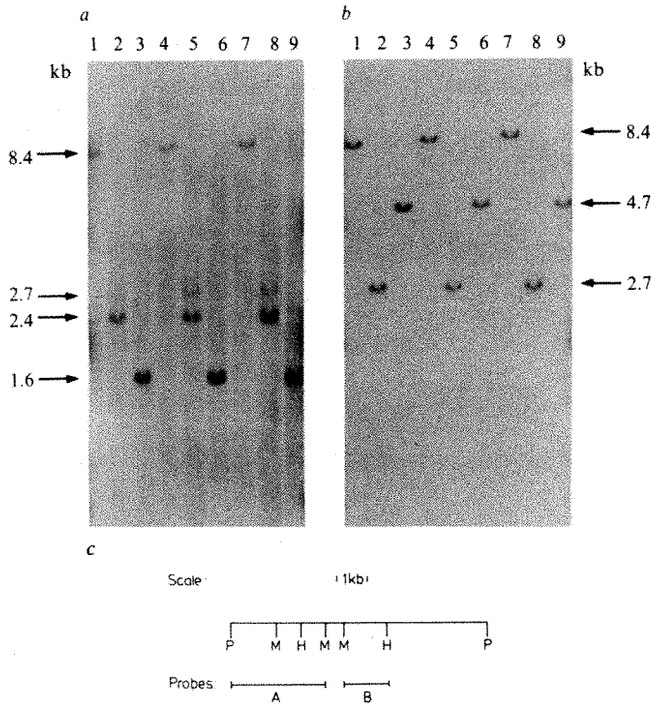

Fig. 6 *a*, *b*, Southern blotting analysis of genomic DNA from three unrelated individuals, KT, PR and AB using the C2 probe A (shown in *a*), or the *Ba* probe B (shown in *b*). *c*, Summary of the restriction map in the region of genomic DNA for which the linkage between the two probes was demonstrated. The restriction enzymes used were as follows: tracks 1, 4, 7: *Pvu*II; tracks 2, 5, 8, *Pvu*II and *Hin*dIII; tracks 3, 6, 9, *Pvu*II and *Bam*HI. The C2 and factor B probes both hybridize to a common 8.4-kb *Pvu*II fragment (tracks 1, 4, 7 in *a* and *b*). When the DNA was simultaneously digested with *Pvu*II and *Hin*dIII, probe A hybridized to two fragments of 2.4 kb and 2.7 kb (tracks 2, 5, 8 in *a*) while probe B hybridized only to the 2.7-kb fragment (tracks 2, 5, 7 in *b*). Both probes hybridized to the 2.7-kb *Hin*dIII fragment as the 3′ end of the C2 gene and the 5′ end of the factor B gene lie within this fragment. Similarly, using DNA digested with *Pvu*II and *Bam*HI, probe A hybridized to fragments of 1.6 kb (tracks 3, 6, 9 in *a*) while probe B hybridized to a 4.7-kb fragment (tracks 3, 6, 9 in *b*) as predicted from the restriction map in Fig. 2.
Methods: 20 μg of DNA was digested to completion with the appropriate one or two restriction enzymes. The reaction mixture was divided into two equal aliquots and one was loaded onto each of two 0.7% 20 cm × 20 cm agarose gels. Each was electrophoresed in parallel and the DNA blotted onto nitrocellulose as described in detail in Fig. 3 legend. DNA fragments used as probes were purified by elution from polyacrylamide thin gels and then nick-translated to a specific activity of $0.2–1.0 \times 10^8$ c.p.m. per μg DNA. Conditions for hybridization, washing and autoradiography were as described in Fig. 3 legend.

Linkage of C2 and factor B genes

A C2-specific 400-bp cDNA probe, pC201, has been isolated that contains sequence coding for a short region of the C2 protein near its C-terminus[18]. The pC201 probe, probe A, was used to identify the position of the C2 locus relative to the genes for C4 and factor B in the cosmid clones already isolated. Probe A hybridized to restriction fragments derived from cos 1a and cos 10, but not 3A3 (results not shown), and the probe site was mapped to within a 2.6-kb region of cos 1a (Fig. 2) that lies approximately 0.5 kb from the 5′ end of the Ba coding sequence. The approximate position of the C2 gene is therefore as indicated by the dotted lines in Fig. 2. Confirmation of the close linkage of the C2 and factor B genes was provided by Southern analysis of genomic DNA of three unrelated individuals using probe A, and a factor B probe that was specific for the 5′ end of Ba (probe B in Fig. 2). The results showed that the C2 (A) and factor B (B) probes hybridize to a common 8.4-kb *Pvu*II fragment (tracks 1, 4, 7, Fig. 6*a*, *b*). When the genomic DNA was simultaneously digested with *Pvu*II and *Hin*dIII, probe A hybridized to a 2.4-kb fragment and more weakly to a 2.7-kb fragment (Fig. 6*a*, tracks 2, 5, 8), while probe B hybridized only to the 2.7-kb fragment (Fig. 6, tracks 2, 5, 8). Similarly, using DNA digested simultaneously with *Pvu*II and *Bam*HI, probe A hybridized to two fragments of 1.6 kb while probe B hybridized to a 4.7-kb fragment (compare Fig. 6*a* and *b*, lanes 3, 6 and 9). These results, which are summarized in Fig. 6*c*, agree with the detailed restriction map already determined for this region of chromosome 6 (see Fig. 2), and therefore confirm that the C2 locus maps within 2 kb of the 5′ end of the factor B gene. These results also indicate that the C2 protein is encoded by a single locus per chromosome.

Discussion

A molecular map of 98 kb of the HLA class III region was prepared by ordering overlapping cloned genomic fragments. Four class III genes were identified in the order C2, factor B, C4z, C4y. These results, combined with results from Southern analysis of genomic DNA, suggests that C2 and factor B are encoded by single loci and C4 is encoded by at least two separate loci. While both forms of C4 gene are common in the population, further analysis will be necessary to determine which genes code for the C4A and C4B serum proteins.

Finding that these four complement genes are located within such a relatively close distance of each other, that is, 30 kb between C4 and factor B and less than 2 kb between factor B and C2, explains the failure to observe cross-overs[21]. It is most likely that the C2 and factor B genes evolved from a common locus as they are very close and the proteins have a similar structure and function. C4 has a function related to but distinct from that of C2 and factor B and although the full amino acid sequence of factor B[20,22] and about a quarter of that of C4 is available[23] there is no obvious similarity. The class I and class II molecules are related in structure to each other (and to the immunoglobulins) and there therefore appears to be at least three distinct types of protein encoded in the MHC, represented by: (1) class I and class II proteins; (2) C2 and factor B; (3) C4A and C4B. The 21-hydroxylase gene has been mapped close to the class III genes in HLA[8] and the neuraminidase gene to class III genes in the H-2 in mice[24] but little information is available on the structures of the corresponding proteins. Their catalytic function seems to be quite unrelated to any of the roles in immunity of the three main classes in the MHC. There is room for more genes between *HLA-D* and *HLA-B*; we hope to identify any coding sequences that may be present and discover whether they are related structurally or functionally to the class I and II or class III genes.

The gene order factor B, C4B, C4A and C2 with C2 nearest the *HLA-B* locus has been proposed by Olaisen *et al.*[25] on the basis of haplotypes existing in the population. Our results corroborate their estimate of the distance between factor B and C4 as 0.04 centimorgans (assuming 1 centimorgan = 10^6 bp), but the order of the genes determined in our analysis places the C2 locus next to factor B, not on the opposite side of the C4 genes.

We thank Dr F. Grosveld for providing the cosmid library of human genomic DNA, also Ms A. Palsdottir, Ms S. Cross and Ms N. Janjua for technical assistance. M.C.C. is recipient of an American Arthritis Investigator Award. D.R.B. is a Beit Memorial Junior Research Fellow.

Transcriptional interference in avian retroviruses—implications for the promoter insertion model of leukaemogenesis

Bryan R. Cullen*†, Peter T. Lomedico* & Grace Ju*

† Department of Microbiology, University of Medicine and Dentistry of New Jersey, Newark, New Jersey 07103, USA

*The downstream (3′) long terminal repeat (LTR) of an avian retroviral provirus is unable to act as an efficient promoter of transcription when a transcriptionally active upstream (5′) LTR is present. This transcriptional interference may explain the observation that only deleted proviruses have been observed inserted adjacent to c-*myc *in avian leukosis virus induced lymphomas of chickens.*

AVIAN leukosis viruses (ALVs) cause neoplastic disease in their hosts only after a long latent period and cannot be shown to cause transformation of cultured cells *in vitro*. This delayed transformation is thus markedly different from that caused by the acutely transforming retroviruses which have been shown to contain oncogenes encoding transforming proteins[1].

Integration of an ALV provirus into the host DNA results in the viral coding sequence being flanked by two long terminal repeats (LTRs)[2,3] (Fig. 1*A*). The viral LTRs contain sequences required for initiation as well as for polyadenylation of viral transcripts and fulfill these roles at the opposite ends of the proviral transcriptional unit[4]. As the proviral LTRs are identical it is possible that the downstream LTR can also act as a transcriptional promoter. The 'promoter insertion' theory (Fig. 1*A*) predicts that ALV causes neoplasms when this downstream LTR transcribes elevated levels of an adjacent *onc* gene analogous to those observed in the acutely transforming viruses[5].

Evidence for promoter insertion oncogenesis has been presented by several workers for lymphomas induced by ALV in chickens[5–7]. Transcripts have been observed containing the U5 region of the ALV LTR and the coding sequence of c-*myc*, the cellular homologue of the transforming gene v-*myc* of the acutely transforming virus MC29. An unexpected result of this research was the finding that the proviruses integrated into the region 5′ of the c-*myc* gene were always defective[5–7]. The observed deletions encompassed different parts of the viral coding region but always appeared to delete the upstream or 5′ LTR. Two theories have been advanced to account for this observed defectiveness[5–7]. One suggestion is that the production of viral gene products by the provirus in a tumour would render it susceptible to detection by the host immune system. However, this appears unlikely as many tumours actively express viral genes encoded by other intact proviruses[5,6]. A second possibility arises from the structure of the LTR (Fig. 2). When the LTR functions as a promoter, RNA polymerase is thought to interact with sequences in the U3 region of the LTR before initiating transcription at the 'CAP' site. ALV mRNAs are polyadenylated at a site 21 bases 3′ to the 'CAP' site[8]. RNA polymerases terminating at this site in the 3′ LTR must transcribe the entire viral U3 region in addition to the 21 bases shared by any initiating transcript (the R region). The observation that

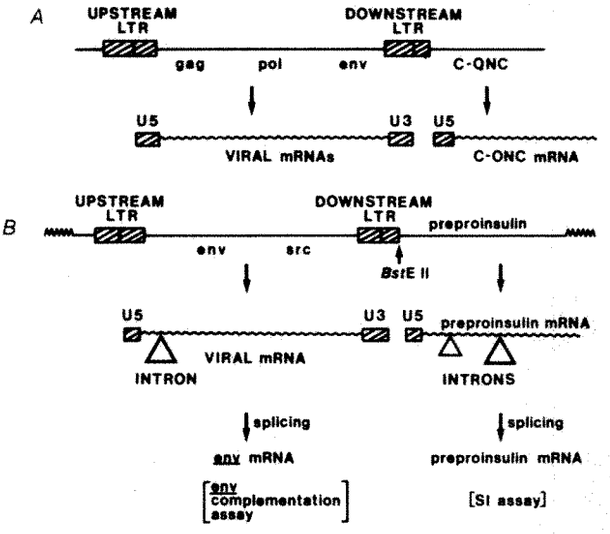

Fig. 1 Experimental strategy for measurement of transcriptional interference. *A*, Expected structure and transcriptional products of an ALV provirus integrated adjacent to a cellular *onc* gene; *B*, Structure of clone pBC8I.
Methods: The proviral region of the clone was constructed as previously described from Schmidt-Ruppin B sequences. The upstream (5′) LTR and *env* gene splice donor site were obtained from clone λSRBtd8[28]. They were joined as previously described[12] to a SR-B DNA fragment from clone pLD6 (D. Stacey, unpublished results) which contains the *env* gene splice acceptor site, the *env* gene, the *src* gene and the downstream LTR. This construction generates a provirus-like structure which is deleted for the majority of the *gag-pol* region of the virus which forms the *env* gene intron. We have previously demonstrated that this deletion does not affect *env* gene transcription and splicing[11]. The rat preproinsulin II gene used contains a *Hin*dIII site inserted in the 5′ non-coding region as previously described[13]. To place the preproinsulin II gene under downstream (3′) LTR control, a *Bst* EII site at the end of the U5 region of the downstream LTR was converted to a *Hin*dIII site. This construction adds an additional 107 bp of 5′ non-coding sequences of retroviral origin to the preproinsulin II transcript.

Table 1 Relative *env* and proinsulin mRNA levels from transfected cells

Lane	Clone	*env* activity		Insulin mRNA synthesis			
		FFU produced*	Per cent	c.p.m. per band	Per cent	Peak area	Per cent
2	pBC8IΔ3	0	0	366	54	237	70
3	pBC8IΔ2	425	0.6	676	100	340	100
4	pBC8IΔ1	52,500	79	225	33	122	36
5	pBC8I	66,000	100	126	19	73	21
9	pBC8I/PA	250	1.3	536	100	306	100
10	pBC8I	18,500	100	149	28	62	20
11	pBC8IΔ3	0	0	287	54	200	66

env activity is shown as the total number of focus forming units produced per transfected culture and as a percentage of the activity of clone pBC8I. Lane nos refer to Fig. 3. Relative insulin mRNA transcription was determined by two methods: peak areas derived by densitometry tracing of the autoradiograph shown using a Beckman DU-8 scanning spectrophotometer, and liquid scintillation counting of actual gel slices from the region of the 170-nucleotide fragment in each lane (values corrected for background counts = 193 c.p.m.). These two measures of insulin mRNA activity are expressed as a percentage of the activity of clone pBC8IΔ2 or pBC8I/PA.

* FFU, focus forming unit.

transcripts extending beyond the 3′ end of the mature mRNA are synthesized during transcription of both retroviral[9] and cellular genes[10] suggests that there is an extensive overlap between the regions involved in initiating and terminating transcription (Fig. 2*A*). This overlap could reduce the ability of the downstream or 3′ LTR to act as an efficient promoter by interfering with initiation of transcription. This inhibition, which we term transcriptional overlap interference, would be relieved by the deletion of the upstream LTR. This deletion may be required if the downstream LTR is to promote sufficient c-*onc* transcription to cause transformation.

Experimental approach

To demonstrate transcriptional overlap interference we have constructed proviral clones in which the upstream and downstream LTRs control the transcription of genes whose levels can be measured independently after transfection into avian cells. The parent plasmid used, pBC8I, is closely analogous to the proposed structure observed after integration of a provirus next to a cellular *onc* gene[5] (Fig. 1*B*). The gene whose transcription is controlled by the upstream LTR is the viral *env* gene whose transcript terminates, as in the proviral case, in the downstream LTR. The gene transcribed under the control of the downstream LTR could, in theory, be any cellular gene. The gene we have chosen to use is the rat preproinsulin II gene. We have previously described sensitive assays for both the viral *env* and the rat preproinsulin II genes[11–13].

The *env* assay is based on complementation of a genetic deficiency in a virus infecting the quail cell line QCl-3. These cells are transformed by the Bryan strain of Rous sarcoma virus [RSV(−)]. The genome of this virus contains *src* but lacks the *env* gene. Virus particles produced by QCl-3 cells are thus not infectious due to the lack of the envelope glycoprotein[11,14]. When QCl-3 cells are transfected with plasmids containing the *env* gene, *env* mRNA may be synthesized leading to production of infectious transforming RSV(−) particles. Stacey *et al.*[14] have shown that the number of infectious virus produced is proportional to the amount of *env* mRNA available in the cell. This

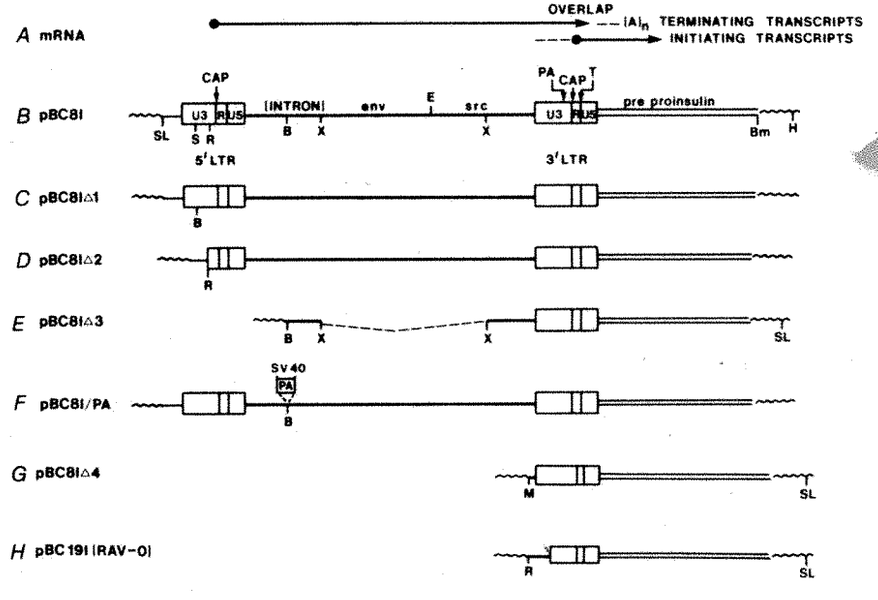

Fig. 2 Structure of the retroviral clones used. *A*, The structure of mRNAs from the *env* and rat preproinsulin II transcriptional units is shown. The region where transcripts initiating in the 5′ LTR would terminate is shown to overlap with the region important for the initiation of transcription in the 3′ LTR. *B*, The parental clone pBC8I is shown. The sequences shown were inserted between the *Sal*I and *Bam*HI sites of pBR322. The approximate location of the *env* gene intron is indicated. E refers to the sequence element noted by Schwartz *et al.*[15] which lies between *env* and *src* in the Schmidt-Ruppin B strain used. (CAP, site of initiation of transcription; PA, polyadenylation signal; T = site of poly(A) addition and termination of viral mRNA). *C*, pBC8IΔ1 was constructed by S_1 exonuclease treatment of the *Sph*I site in the 5′ LTR U3 region followed by insertion of a *Bgl*II linker DNA molecule. This results in a net insertion of 4 bp. *D*, pBC8IΔ2 was constructed by cleavage of the 5′ LTR U3 region with *Pvu*I followed by S_1 exonuclease digestion and religation. A clone retaining the *Eco*RI site was then selected, and nucleotide sequence analysis revealed the deletion of 191 bp of the U3 region 5′ to the *Eco*RI site. *E*, pBC8IΔ3 was created by deletion of the entire 5′ LTR region and viral structural sequences, including element E[15], located between the *Xho*I sites shown. The clone retains ≈1.5 kb of viral gene sequences in addition to the 3′ LTR. *F*, pBC8I/PA contains a 237 bp *Bcl*I to *Bam*HI fragment from SV40 ligated into a *Bgl*II site in the *env* gene intronic region. This fragment has the SV40 late polyadenylation/termination signal inserted in the sense orientation relative to the *env* gene. *G*, pBC8IΔ4 was derived from pBC8IΔ3 by deletion of all viral structural gene sequences 5′ to a *Mst*II site located ≈40 bp from the U3 region of the 3′ LTR. *H*, pBC19I contains the previously described[12] LTR of the endogenous virus RAV-0 ligated to the rat preproinsulin II gene in the same fashion used for the exogeneous virus LTR. It retains ≈130 bp of chicken DNA bounded by an *Eco*RI site. Clones pBC8IΔ3, pBC8IΔ4, and pBC19I were cloned between the pBR322 *Eco*RI and *Bam*HI sites in the opposite orientation to the other clones described relative to pBR322. pBR322 (∿); retroviral sequences (—); preproinsulin sequences (=); S, *Sph*I; X, *Xho*I; *R*, *Eco*RI; H, *Hin*dIII; SL, *Sal*I; B, *Bgl*II; M, *Mst*II; Bm, *Bam*HI.

in turn is a reflection of the ability of the transfected plasmid to synthesize *env* mRNA.

The S_1 nuclease assay used to quantitate preproinsulin mRNA synthesis involves the use of a DNA probe uniquely end-labelled in an exon of the insulin gene[13]. As the probe extends through an intronic sequence of the insulin gene, annealing to correctly spliced preproinsulin mRNA synthesized in the QCl-3 cells followed by S_1 treatment results in the quantitative production of a band of characteristic size on a denaturing acrylamide gel. This S_1 assay does not distinguish between proinsulin transcripts originating in the 3′ LTR and any readthrough transcripts which might initiate in the 5′ LTR. As all the plasmid constructs contain the same preproinsulin transcription unit (Fig. 2), the steady-state levels of insulin mRNA as determined by the S_1 assay should be an accurate measure of the relative promoter activity of each clone tested.

Mutation of the upstream LTR

To determine whether the transcriptional activity of the upstream LTR affects that of the downstream LTR, we introduced mutations into the upstream LTR of plasmid pBC8I and measured the affect of these lesions both on *env* and preproinsulin gene trancription using the two independent assays. The different deletions introduced into pBC8I are outlined in Fig. 2.

In clone pBC8IΔ1 we have introduced a minor change into the U3 region of the upstream LTR by inserting a *Bgl*II linker DNA molecule into the *Sph*I site. This modification has been shown by DNA sequence analysis to result in the net insertion of four base pairs (bp). Clone pBC8IΔ2 has been shown by DNA sequence analysis to contain a deletion of the U3 region of the LTR extending up to the *Eco*RI site, within 57 bp upstream of the CAP site. In clone pBC8IΔ3 the entire upstream LTR and nearly all the viral structural gene sequences, including the *env* gene, are deleted leaving only the downsteam LTR intact.

All modifications of the upstream LTR reduced *env* transcription relative to pBC8I, as determined by the *env* complementation assay (Table 1). In clone pBC8IΔ1 *env* synthesis was reduced only slightly. Clone pBC8IΔ2, although it retains part of the U3 region of the LTR including the 'TATA' box, shows only ≈1% the *env* gene activity of the undeleted clone. This supports the contention that the U3 region of the LTR contains sequences essential for promoting viral mRNA synthesis. As expected, clone pBC8IΔ3, which has a deleted *env* gene, produced no *env* activity. As may be seen in Fig. 3, mutation of the upstream LTR has the opposite effect on transcription of preproinsulin mRNA from the downstream LTR. Clone pBC8IΔ1 (lane 4) shows a small elevation in preproinsulin mRNA synthesis while clone pBC8IΔ2 (lane 3) and pBC8IΔ3 (lane 2) show clearly elevated levels compared to the parental clone pBC8I (lane 5). Clone pBC8IΔ3 shows consistently slightly lower levels of preproinsulin mRNA synthesis than clone pBC8IΔ2. The reason for this is unknown but may be due to the deletion of viral structural gene sequences in pBC8IΔ3 which have been suggested to affect transcription[15]. Alternatively this difference may be explained by the fact that, for technical reasons, pBC8IΔ3 is inserted into the plasmid vector in the opposite orientation compared to the other clones. Superinfection of QCl-3 cells with an avian leukosis virus has no affect on preproinsulin RNA transcription from transfected DNA templates (results not shown), demonstrating that envelope glycoprotein does not directly affect insulin mRNA synthesis.

As noted previously, the S_1 assay for preproinsulin expression would measure transcripts which initiate in the 3′ LTR as well as any readthrough transcripts which initiate in the 5′ LTR. Read through transcripts which fail to terminate using the LTR polyadenylation signal have been observed in avian cells[9]. The contribution of readthrough transcripts in this assay would result in an underestimate of the differences between intact and deleted LTR clones, so that the ≈5-fold difference in proinsulin mRNA transcription between pBC8I and pBC8IΔ2 may represent the minimum effect due to overlap interference.

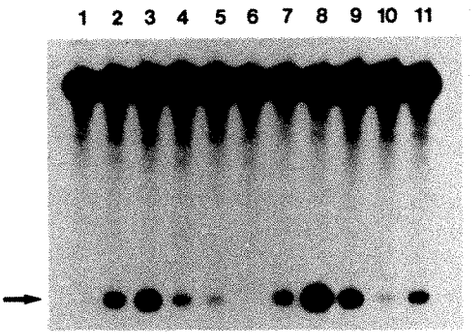

Fig. 3 Effect of 5′ LTR promoted transcription on 3′ LTR activity. Autoradiograph of S_1 assay acrylamide/urea gel. Lane 1, prI2/SV40-46; 2, pBC8IΔ3; 3, pBC8IΔ2; 4, pBC8IΔ1; 5, pBC8I; 6, pBC8; 7, 5 ng of rat insulinoma (RI) poly(A+)-RNA; 8, 25 ng of RI poly(A)$^+$ RNA; 9, pBC81/PA; 10, pBC8I; 11, pBC8IΔ3. Lanes 1–5 and lanes 9–11 contain RNA samples derived from two independent transfection experiments. Relative *env* and proinsulin mRNA levels from transfected cells are given in Table 1.
Methods: QCl-3 cells are seeded at 9×10^6 cells per 100 mm dish 20 h before transfection. 5.8 μg of clone pBC8I DNA or equimolar quantities of other plasmid DNAs were taken up in 2 ml of phosphate buffered saline (PBS) containing 1 mg ml^{-1} of DEAE-dextran. The monolayer of QCl-3 cells was washed once with warm PBS, the DNA solution was added to the cells, and they were incubated at 37 °C for 30 minutes with occasional gentle shaking. At this time, 25 ml of growth media was added to the cells and they were incubated for a further 2.5 h before refeeding with fresh growth media. Media samples for use in the *env* assay were taken at 72 h post-transfection. These were assayed for focus forming unit (FFU) production on chick embryo fibroblasts (CEF) as previously described[11,14]. As the *env* gene used is of the B serotype, the viruses produced are infectious for CEFs but not for quail cells and thus no spread can occur in the transfected culture[29]. After media sampling, RNA was isolated from the QCl-3 cells as described[13]. Total RNA yields were quantitated by UV adsorbance, gel analysis, and dot blots using a *gag*-specific probe as the internal standard. Using 10 μg of total RNA from each transfected culture, preproinsulin mRNA in each sample was quantitated by S_1 mapping[13,30,31]. The probe used was a 750 bp fragment uniquely 3′ end-labelled at a *Bam*HI site in the coding region and extending to a *Hha*I site on the other side of the 499 bp intron in the preproinsulin II gene. Correctly spliced preproinsulin mRNA will anneal to the labelled anti-sense DNA strand, and nuclease S_1 will digest the unhybridized intronic sequences. A 170 nucleotide labelled fragment (indicated by arrow) is protected in proportion to the quantity of preproinsulin mRNA present in the reaction[13].

Clone pBC8, which contains the same retroviral sequences as pBC8I but lacks the insulin gene, is negative in the preproinsulin RNA S_1 assay (Fig. 3, lane 6). If the preproinsulin gene is inserted in the inverted orientation relative to the LTR, no proinsulin mRNA is detectable (results not shown). Interestingly, clone prI2/SV40-46, in which the preproinsulin gene is under Simian virus 40 (SV40) early promoter control, also shows no detectable preproinsulin transcription in avian cells (Fig. 3, lane 1). This contrasts with the situation in monkey cells where this construction is quite active[13]. It is also of interest to note that the hybrid LTR U5 region-preproinsulin mRNA transcribed from the downstream LTR is able to efficiently program the synthesis and secretion of rat proinsulin (results not shown).

These results are consistent with the hypothesis that transcription from the upstream LTR in an integrated provirus inhibits transcription from the downstream LTR due to overlap interference. To prove this point directly, we have constructed clones in which transcription from the upstream LTR was terminated before reaching the downstream LTR.

Insertion of a transcriptional terminator

We have previously presented evidence that modification of the size of the *env* gene intron either by deletion or insertion of exogenous sequences has only limited effect on production of spliced *env* mRNA, given that the inserted sequences do not

Table 2 Relative *env* and proinsulin mRNA levels in the transfected cells

		env activity		Insulin mRNA synthesis	
Lane	Clone	FFU produced	Per cent	Peak area	Per cent
1	PBC8I	131,520	100	81	23
2	pBC8I/PA	260	0.2	346	100
5	pBC8IΔ4	0	0	308	100
6	pBC19I	0	0	46	15

Data are given as in Table 1. Lane nos refer to Fig. 4. Relative insulin mRNA levels were determined by peak area calculation using a DU-8 scanning spectrophotometer. mRNA levels are expressed as a percentage of clone pBC8I/PA (lanes 1 and 2) or pBC8IΔ4 (lanes 5 and 6).

interfere with transcription or contain splice sites[11]. Thus, if we insert a transcriptional terminator into the *env* intron of clone pBC8I, reduced *env* production should be a measure of the premature transcriptional termination produced by this insertion. This is because any transcripts that avoid premature termination would be expected to be spliced in the normal manner, thereby eliminating sequences inserted into the intron and producing normal, functional *env* mRNA.

The transcriptional terminator we have chosen to use is derived from SV40 DNA. A 237 bp fragment containing a polyadenylation site was isolated following cleavage of SV40 DNA at the unique *Bcl*I and *Bam*HI sites. This fragment, which contains no splice sites used by SV40[16], was inserted into the *env* gene intron in clone pBC8I such that the polyadenylation site used in SV40 late gene transcripts was in the sense orientation, thereby yielding clone pBC8I/PA (Fig. 2*F*). Transfection with DNA from clone BC8I/PA results in *env* production reduced by ≈99% relative to clone pBC8I (Table 1) but yields an increase in preproinsulin mRNA synthesis comparable to clone pBC8IΔ2 (Fig. 3). Thus, when transcription from the upstream LTR is prematurely terminated, the inhibition of the promoter activity of the downstream LTR is correspondingly relieved.

Endogenous retroviral LTR

The difference between the levels of transcription promoted by the 3′ downstream LTR in the intact versus deleted clones is only about 5-fold in these experiments. This relatively small difference must be contrasted with the 30- to 100-fold increase in c-*myc* mRNA above basal levels found in the chicken bursal lymphomas[17]. However, small differences in the level of gene expression appear to have biologically significant consequences. We have previously presented evidence that the LTR promoter of the endogenous virus RAV-0 is ≈10-fold less efficient than the exogenous virus LTR in the *env* assay[12]. RAV-0, which also produces 10-fold less mRNA in infected cells *in vivo*, does not cause tumours in chickens[18]. Evidence has been presented by ourselves and others[12,18,19] that this lack of oncogenicity may be due to the lower efficiency of the RAV-0 LTR promoter.

To test the efficiency of the RAV-0 LTR for proinsulin transcription, two additional clones were constructed (Fig. 2,*G*, *H*). pBC8IΔ4 has a deletion of the entire viral transcriptional unit upstream of the 3′ LTR, constructed by the removal of the remaining viral structural gene sequences in pBC8IΔ3. Only ≈40 bp of viral sequences remain in addition to the 3′ LTR. Clone pBC19I contains the RAV-0 LTR in place of the exogenous Schmidt-Ruppin B LTR present in all other constructs, and is in the same orientation as clone pBC8IΔ4.

Data from a transfection experiment using these clones are shown in Fig. 4. In the *env* assay, pBC8I produces the greatest number of focus forming units while, as before, pBC8I/PA gives significantly less activity. pBC8IΔ4 and pBCI9I yield no *env* activity as they lack the *env* gene. Quantitation of the preproinsulin mRNA assay (Table 2) shows that pBC8I/PA (lane 2)

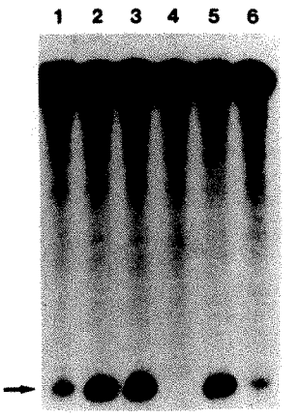

Fig. 4 Comparison to an endogenous retroviral LTR. Lane 1, pBC8I; 2, pBC8I/PA; 3, insulin mRNA positive control; 4, pBC8; 5, pBC8IΔ4; 6, pBC19I. Relative *env* and proinsulin mRNA levels in transfected cells are given in Table 2.
Methods: Transfections were performed as outlined in Fig. 3 with the following minor modifications. Half as much DNA was transfected per culture (2.9 μg of pBC8I and equivalent molar amounts of other clones) and the cultures were treated for 2.5 h with 80 μM chloroquine in media as described by Luthman and Magnusson[32], which results in an increase in transfected DNA uptake. Nine μg of total RNA were analysed per lane.

produces the greatest amount of proinsulin transcripts, about 5-fold more than the pBC8I clone (lane 1). Transcription from pBCI9I yields a low level of insulin mRNA (lane 6), ≈7-fold less than pBC8IΔ4 (lane 5). Thus, the relatively small difference in insulin transcription between the RAV-0 LTR and the exogenous LTR in the deleted clones, which appears sufficient to distinguish a non-oncogenic from an oncogenic LTR promoter, is comparable to the difference caused by transcriptional interference in the downstream LTR of an exogenous retrovirus.

Implications for ALV leukaemogenesis

We have presented evidence that viral mRNA transcription extending into the downstream LTR of a provirus-like construct restricts the ability of this LTR to function as an efficient promoter. The inhibition, which we term transcriptional overlap interference, is removed if the upstream LTR is damaged or deleted or if a transcriptional termination signal is inserted between the LTRs. The increased ability of the downstream LTR of an integrated provirus to act as a promoter following deletion of the upstream LTR provides an explanation for the observation that only deleted proviruses are observed inserted upstream and in the same orientation to c-*myc* in lymphomas of chickens[5–7].

Alternative configurations of the integrated provirus relative to c-*myc* have been described by Payne *et al.*[20]. One bursal lymphoma contained a provirus downstream of c-*myc* in the same orientation, while others had the proviral DNA upstream of c-*myc* in the opposite orientation. In the former case, the provirus was deleted, leaving only the 3′-LTR and adjacent viral DNA. In addition, at least 15 kb of cellular DNA on the 3′ side of c-*myc* was also lost. In the latter cases, deletions of the provirus are also observed. These deletions are, however, internal in most, though not all, cases[6,20]. These two alternative configurations do not allow the direct use of the LTR as the promoter for c-*myc* expression, as predicted by the promoter insertion model. Thus, deletion of LTR sequences would not be required to relieve overlap interference in these cases.

The pathology of lymphoid leukosis in chickens sheds additional light on how neoplastic transformation may proceed[21]. Following infection of newborn chicks by ALV, the earliest histologic evidence of the preneoplastic state is the appearance of transformed follicles in the bursa. A small proportion of these follicles (≈2%) give rise to nodules which latter progress to a disseminated lymphoid leukosis. This multi-step progression to lymphoid tumours may represent discrete events at the

molecular level. Our data are consistent with the hypothesis that malignant transformation may begin by the rare random integration of an ALV provirus adjacent to c-*myc*, which would interrupt the c-*myc* locus. This first event would result in the disruption of normal cellular regulation of the c-*myc* allele, followed by increased expression of c-*myc* promoted by the 3′ LTR of the integrated provirus. A second random event, deletion of the LTR, would cause an additional increase in c-*myc* transcription. It has previously been observed that integrated proviruses may spontaneously delete part of the viral sequence, including an LTR, at a low frequency[22]. These two discrete events may be necessary to allow c-*myc* transcription promoted by the remaining LTR to increase to levels sufficient to cause malignant transformation. Subsequent events, such as the postulated activation of a second oncogene[23], may also be required to produce leukosis.

The control of gene expression

The frequency with which the phenomenon of transcriptional overlap interference occurs remains to be determined. A process analogous to overlap interference has been reported in procaryotes where it has been shown that the upstream P_L promoter of prophage λ inhibits the initiation of transcription at downstream *gal* promoters[24]. Interference between overlapping transcriptional units has also been observed in other prokaryotic operons[25,26]. Therefore, the phenomenon of overlap interference appears not to be unique to the avian provirus but could represent a novel mechanism for the control of gene expression. Transcriptional overlap interference could be used to coordinately regulate two adjacent, overlapping transcriptional units by controlling only the upstream promoter directly. The downstream promoter would become progressively more active as the upstream promoter was repressed and less active as the upstream promoter was induced. A possible example of this phenomenon has been observed in yeast[27]. The 5′ gene in this case is the repressible acid phosphatase gene *PHO*5 while the 3′ gene is the acid phosphatase gene *PHO*3. These genes are closely linked in yeast and were cloned together on a single 8 kb DNA fragment. *PHO*3 is expressed in yeast growing in media containing phosphate while *PHO*5 is repressed. If phosphate is removed *PHO*5 is induced and *PHO*3 is no longer detectable[27]. It has now been demonstrated (R. Kramer and K. Bostian, personal communication) that if the upstream *PHO*5 gene promoter is deleted, the *PHO*3 gene continues to be transcribed in the absence of phosphate. These observations are consistent with the use of transcriptional overlap interference as a mechanism in the coordinate control of differential gene expression.

We thank S. Kahn, S. McAndrew and F. Esch for assistance in DNA sequence analysis, and D. Stacey for the use of clone pLD6. We also thank A. Skalka and R. Kramer for helpful discussions and D. Andriola and S. Sturdivant for typing the manuscript.

A new kind of natural radioactivity

H. J. Rose & G. A. Jones

Department of Nuclear Physics, University of Oxford, Oxford OX1 3RH, UK

From a systematic study of the properties of nuclei heavier than lead, we have concluded that, in one or two cases, radioactive decay by emission of a particle heavier than the α-particle might be observable in competition with the latter. We have observed such decay in ^{223}Ra which occurs in the natural radioactive series emanating from ^{235}U. Two 'by-pass' modes seem likely: emission of ^{14}C, to ^{209}Pb, with a *Q*-value of 32 MeV; and of ^{12}C, to ^{211}Pb, with a *Q*-value of 28 MeV. (Emissions of ^{13}C and ^{15}C from the same nucleus have *a priori* emission rates similar to that of ^{12}C, but the emission of α-like nuclei seems more likely.) In this study we have used a solid-state counter telescope to identify the charge of the particle emitted, and, for greater convenience, a source of ^{227}Ac (half life 21 yr), with which the lower members of the series, including ^{223}Ra, are in secular equilibrium. We have observed particles identifiable as carbon ions and, from their energy and emission rate, they are ^{14}C rather than other carbon isotopes. The branching ratio for emission of ^{14}C nuclei relative to α-particles from ^{223}Ra is $8.5 \pm 2.5 \times 10^{-10}$, corresponding to a reduced width (preformation probability) smaller by a factor of ~10^5 to 10^6.

The obvious problem in the detection of rare modes of decay is to distinguish between these modes and the multiple pile-up of α-particle pulses. Using techniques familiar in nuclear experimentation, we were able to reject events due to pile-up provided that individual α-particles in the event were separated in time by over ~100 ns. Even so, with a detected α-particle rate of ~4,000 s^{-1} we observed, over a counting period of several months, events extending out as far as quadruple pile-up of total energy up to 28 MeV. However, the ratio of ionization in the thin (ΔE) counter of the telescope to that in the thick ($E - \Delta E$) counter for a carbon ion, is quite different from the same ratio arising from α-particle pile-ups of the same or nearly the same total energy, so that all the α-events including multiple pile-up, are clearly segregated from carbon events in a $\Delta E, E$ plot. In any case, the total number of quadruple α-pile-ups to within 5 MeV of our detected events was small; see Fig. 1.

Another problem, which resulted in our doubting the energy measurements of, and consequently rejecting, a run of several months, is that of radiation damage occurring in the semiconductor detectors exposed to a high counting rate over a long period of time. As the ionization density for α-particles is at its highest very close to the end of the range, the $E - \Delta E$ counter responds to damage more quickly than the ΔE counter. Because the α-particles and the carbon ions at the energies of the experiment have much the same range, one cannot reduce the $E - \Delta E$ counter in thickness until it no longer stops the α-particle, but

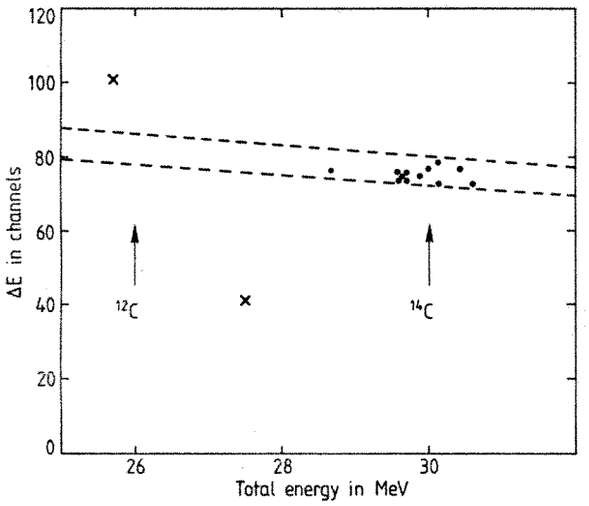

Fig. 1 Contents of the two-dimensional array ΔE versus E_{total} after a run of 189 days. The dotted line indicates the allowed region for carbon ions and the arrows indicate the total energies expected for ^{12}C and ^{14}C emissions in the decay of ^{223}Ra. The lower of the two crosses represents a quadruple pile-up. Below the total energy displayed, large numbers of triple and double α-pile-ups were recorded. Single α-events (and, in part, even double α-pile-ups) were biased out on the analogue side to avoid deadtime problems on the digital side. The upper cross is an event which was recorded during a thunderstorm which affected the mains badly. A run of 194 days was made before this one, yielding 8 events and, in addition, a run of approximately half a year was performed to investigate possible cosmic ray-induced events. Channel 77 in $\Delta E \equiv 6.7$ MeV, which is exactly as expected for 30 MeV ^{14}C. Detector characteristics: The dead layer of the ΔE detector (200 mm^2 active area, 8.2 μm sensitive thickness) was determined to lie between 0.3 and 0.8 μm. In addition a protective layer of gold of thickness 20 $\mu g\,cm^{-2}$ was evaporated on the source and 15 $\mu g\,cm^{-2}$ carbon film inserted between the source and the ΔE detector. An extra 30–40 $\mu g\,cm^{-2}$ of gold is present on the E-detector (300 mm^2 active area). This gives a total of 150–250 $\mu g\,cm^{-2}$ of effective dead layer (Si equivalent) and an energy loss of ^{14}C ions of 0.5–0.8 MeV. The source of strength 3.3 μCi gave a counting rate of $\approx$4,000 s^{-1}, corresponding to an effective solid angle of detection of $\approx 1/3$ sr.

still stops the higher charged particle (a technique used in fission measurements, using gas counters, in order to enhance the fission pulses relative to α-pulses and so overcome the effects of pile-up). After having experienced this effect with a thick detector which had been much used previously, the problem was overcome by using new counters and monitoring closely the single α-pulses in both detectors. While the events detected in the first run were clearly due to carbon ions, the energy measurements were uncertain to ~2.5 MeV, but in the second run the energy measurements were reliable and close to the expected value for ^{14}C emission, that is, 30 MeV, after allowing for the recoil energy of the daughter nucleus (see Fig. 1). The runs were done automatically using on-line LSI-11/Camac-based two-dimensional storage techniques. To mitigate against hardware failure, the results were read out and up-dated every 12 h. In the event of an error occurring during the 12-h period, the computer was programmed to reject that 12-h run and to carry on from the previously stored data.

Before discussing further the energy measurements, the accompanying table is of interest. Of all the exotic emissions possible from the radioactive chain we are using, we have listed those which are most likely to be observed and have given the ratio of their Gamow factors to the appropriate Gamow factors for α-emission for three values of the parameter r_0 in the expression for channel radius, $r = r_0(A^{1/3} + a^{1/3})$, where a represents the mass number of the emitted particle and A that of the daughter nucleus (see Table 1). It is immediately evident that emission of ^{14}C from ^{223}Ra virtually selects itself as the

Table 1 Possible strange decay modes in the ^{235}U natural $(4n+3)$ radioactive series and their relative probabilities for observation

The full Q-values were used in the computations. The major α-modes are known to lead to ground states and/or states nearby (that is, within <300 keV above ground state); l-values can be neglected in the strange decay modes; the considered α-decays for normalization are all leading either to the ground state (or a state nearby) with an $l=0$ or $l=2$ branch, the branching ratio being sufficiently strong for the order-of-magnitude estimates presented.

explanation of our data; emission of ^{12}C, ^{13}C or ^{15}C from the same parent are equally likely (*a priori*) to within a factor of 10, but considerably less so than ^{14}C emission. Since sequences of three α-particles often occur in radioactive chains, one may reasonably expect the preformation probabilities for ^{8}Be, ^{12}C and ^{16}O to be considerably higher than for other configurations; but there seems to be no good reason to assume similar enhancements for ^{13}C and ^{15}C relative to ^{14}C. Considering the data in Table 1, the most likely emission observed is ^{14}C, with ^{12}C (and a more favourable preformation probability) the next most likely. Therefore, we have given the location of the ^{12}C group in Fig. 1.

If we now introduce our measured ratio of $8.5 \pm 2.5 \times 10^{-10}$ carbon nuclei per α-particle and compare it with the Gamow ratio of 1×10^{-5} to 2×10^{-3} (see Table 1) for ^{14}C, 7×10^{-12} to 1×10^{-9} for ^{12}C, 1×10^{-10} to 2×10^{-8} for ^{13}C, and 5×10^{-12} to 2×10^{-9} for ^{15}C, we conclude that the preformation probabilities for ^{12}C, ^{13}C and ^{15}C need to lie somewhere in the range 0.1–10 times that for the α-particle; we consider this to be preposterous for ^{13}C and ^{15}C and unacceptable for ^{12}C. Thus, we conclude that the emissions are of ^{14}C from ^{223}Ra with a preformation probability in the range of 7×10^{-5}–4×10^{-7} times that for α-emission from the same nucleus. These considerations relegate the energy calibration to a somewhat minor role, although important to us as it is a measure of confidence in what we are doing.

The energy calibration was made using ^{241}Am α-particles of 5.48 MeV, and extrapolating up. This may seem rather risky when it is realized that the source was covered by thin gold and carbon foils, to prevent source material sputtering onto the ΔE counter due to daughter recoil on α-decay, and in addition the detectors themselves have unknown dead layers. However, serendipity occasionally comes to the aid of the experimenter; from tables of energy losses of charged particles, it turns out that ^{241}Am α-particles and ~31-MeV ^{14}C ions have almost the same ratio of dE/dx to E thus the fractional energy loss for each particle is the same. Hence the pulse outputs should scale as the total energies independently of the unknown energy losses, provided they are fairly small (extrapolation from energy to energy even for different types of particle is well established for Si semiconductor detectors). As the unknown energy loss is estimated (see Fig. 1 legend) to be of the order of $\leq$1 MeV for carbon ions of these energies, a linear scaling through the origin and the 31-MeV point will produce very little error in the neighbourhood of 30 MeV. It is, therefore, highly gratifying to us that our extrapolated calibration assigns to the closely

grouped events observed almost exactly the energy required for ^{14}C emission from ^{223}Ra.

Finally, we feel that similar by-pass decays must occur in other nuclides in this region, chiefly to the doubly magic nucleus ^{208}Pb and its near isotopes in order to make use of the extra stability of the daughter nucleus. As the neutron excess increases rapidly with Z, the parents will tend to be more neutron-deficient than nuclides in the naturally occurring sequences which are on the neutron-rich side of the valley of stability. The likely candidates for by-pass decay will probably need to be man-made (or arise in series in which the ultimate parent is man-made) rather than occur naturally.

We acknowledge the considerable help and advice of our entire laboratory and particularly thank Mr T. Thacker and Mr P. Dyer. The source was supplied by the Chemistry Division of AERE, Harwell.

Power spectrum of long-period solar oscillations and 160-min pulsations during 1974–82

A. B. Severny, V. A. Kotov & T. T. Tsap

Crimean Astrophysical Observatory, Nauchny, Crimea, 334413, USSR

We report here the results of solar oscillation observations carried out between 1974 and 1982 using the Crimean solar magnetograph. We have eliminated all peaks of telluric origin from the mean power spectrum; of the remaining 32 dominant ($\geq 2\sigma$) peaks, 19 are of solar origin and 13 are partly blended with the atmospheric peaks. We found that 10 solar peaks are in very good agreement with the modes g_{10}–g_{20} of degree $l = 4$ calculated by Christensen-Dalsgaard *et al.*[1] for the solar model C with the envelope enriched in heavy elements by accretion. Deviations of the observed long-period oscillations from a linearity can be appreciable, leading to the appearance of combination frequencies. The dominant 160-min peak seems to be excited by a strong 'double' resonance of $2g_8$ mode of model C with a combination frequency, and two other combination frequencies of modes $1g_1$ and $2f$ including the unstable mode $l = 1$. As model C is also in good agreement with the neutrino experiment, we suggest that this could be considered as the most appropriate model of the Sun. In contrast to previous detailed studies of solar pulsation with the particular 160.01-min period[2,3], the emphasis here is on the search for other possible long-period solar oscillations of low degree. These oscillations are thought to be bound to the regions beneath the convection zone and penetrate to the Sun's core which makes them a powerful tool for analysing the solar internal structure and the evolution of the Sun.

The Crimean solar magnetograph with a special Doppler shift modification[4] is being used continuously to measure the wavelength difference between two profiles of the same nonmagnetic spectral line λ 5,124 Å—one from the central circular area ($0.66R_\odot$) of the solar disk, and the other from the remaining annular portion of the solar disk[5]. The observations described here were made in 1974–82 during 473 days spanning 2,719 h (for data processing see ref. 5). The double solar magnetograph was used to discriminate real solar peaks in power spectrum from false peaks produced mainly by the Earth's atmosphere (such as fluctuations of transparency and differential extinction). Simultaneous observations over 7 yr of the telluric O_2λ6,879 Å line (1975–82, 905 h in total) were carried out and reduced in a similar way.

The power spectra of the mean 5-min-interval residuals (centre minus limb data) were calculated for both spectral lines in three ways: (1) independent mean power spectra were obtained for each annual data set; (2) the total 1974–82 data set was considered and the coherent spectrum calculated (with a resolution of 1 nHz); (3) nine annual power spectra were normalized and subsequently averaged. The later spectra (with an effective resolution of ~0.07 μHz) in the period range 110–210 min is shown in Fig. 1. Besides the apparent presence of a dominant peak at 160.0 min, there are several other peaks of comparable and lower amplitudes.

To discriminate the real solar peaks of this spectrum we used the similar spectrum of the telluric λ 6,879 Å oxygen line. However, before comparing the solar and atmospheric power spectra we have considered the meaning of the 'coincidence of peaks'. A careful study of the positions of previously selected 93 dominant peaks in the solar and telluric power spectra, based mainly on the comparison of above mentioned three types of spectrum, indicated that the real error in the period's value is $|\Delta T| \leq 0.5$ min for periods ≈160 min. We were able to assign 37 peaks to the telluric power spectrum and they were thus excluded. The 17 peaks observed only at Stanford (1977–80 data) or only at the South Pole were also excluded. Seven peaks that were observed but were not identified with theory[1] were not considered. Of the remaining 32 peaks (listed in Table 1),

Table 1 Real solar peaks

No. of peak	Dominant peaks of solar spectrum (1974–82) T(min)	Identification with the model C $l = 4$ (O–C, min)	$l g_n - l' g_i$
1	200.5		$2g_2$–$2g_4$ (200.6); $2g_1$–$4g_5$ (200.5); atm?
2	200.0 S	$g_{20} = 199.9$ (0.1)	$4g_{20}$
3	196.3		$1g_2$–$4g_{21}$ (196.5)
4	192.6*		$2g_3$–$4g_{14}$ (192.3); atm?

* Peaks not denoted on Fig. 1 (amplitudes ones which are dominant ($>2\sigma$) in the string of 8-year data (1974–81)). Separate peaks 153.3 and 152.9 min have been combined in one peak 153.1 min in accordance with resolution adopted. The same was done with the peaks 170.8 and 171.2 min.

© 1984 Macmillan Journals Ltd

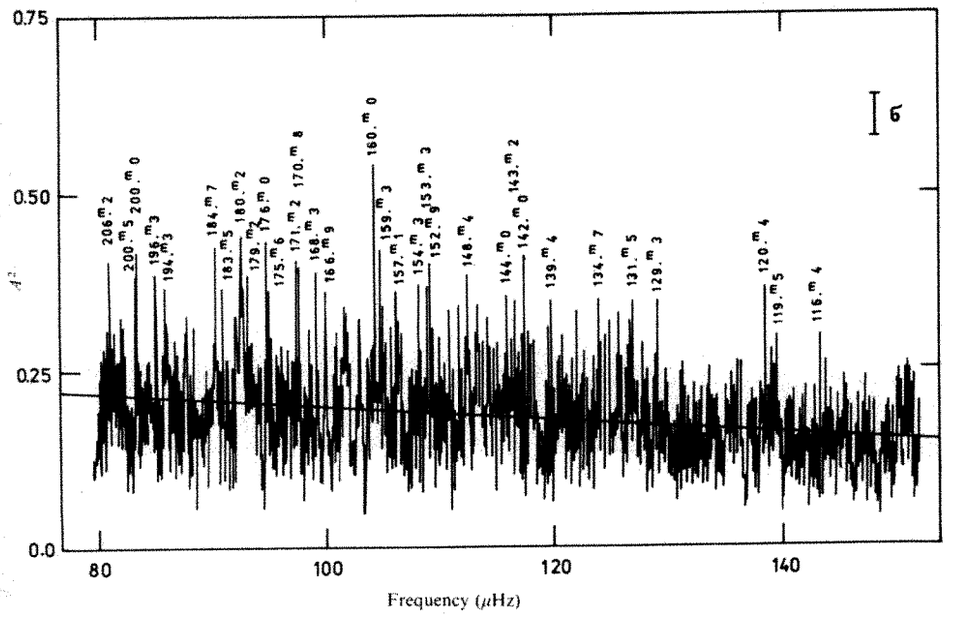

Fig. 1 Power spectrum of solar oscillation, 1974–82. The numbers indicate periods (in min) of dominant peaks, exceeding the 2σ confidence level. Straight line represents the mean level, vertical bar corresponds to 1σ deviation from the mean level.

13 are partly blended with the atmospheric peaks (notified 'atm?') and 19 can be considered as of real solar origin. All these 32 peaks (periods, in minutes) are given in Table 1. Those 12 peaks which coincide with those observed at Stanford (during 1977–80) are denoted (by S). The data obtained at the South Pole are not used here because they are rather scarce and add no essential features either to Table 1 or the echelle-diagram (except one point with the period 204.0 min; the other four points coincide well with our points). Table 1 contains 23 peaks from the 1974–82 data (see Fig. 1) and nine peaks from the 1974–81 data which are dominant for all this time interval.

To estimate the noise level of the power spectrum shown in Fig. 1, the mean of amplitudes and r.m.s. deviation σ_0 associated with it were computed (zero-order approximation). Then all the peaks exceeding the $3\sigma_0$ level were excluded and the new mean amplitude and corresponding r.m.s. (σ_1) were recalculated. Then, all peaks exceeding the $2\sigma_1$ level were excluded, and the final mean amplitude and final r.m.s. noise $\sigma \approx 0.054$ ($m^2\,s^{-2}$) were computed (see Fig. 1 where 32 peaks with amplitudes $A^2 \geq 2\sigma$ are denoted), 23 of these peaks which can be identified are included in Table 1. These 23 peaks are also present in the 1974–81 data which show nine more significant and identified peaks. (Note that the amplitude of 160-min peak is $\approx 6\sigma$).

Having tabulated the periods and considered them as eigenmodes of solar model oscillations, one can immediately find close correspondence of these observed periods with those calculated by Christensen-Dalsgaard *et al.*[1] for their model C of the Sun for degree $l = 4$ and orders ranging from g_{10} to g_{20}. The values 4 g_n calculated in (ref. 1) and taken from their Table 3 are presented in Table 1, as well as on the echelle—diagram (see Fig. 2, where the dashed straight lines connect theoretical values).

There is satisfactory agreement between theoretical 4 g_n values and a string of the observed ones: the mean O–C = 0.05 min for all 10 values. The probability of chance coincidence, within a tolerance ±0.5 min, here $\leq (\frac{1}{2})^{10} \sim 10^{-3}$. The Monte Carlo method, for the determination of probability of the simultaneous chance coincidence, gives the value $\sim 3 \times 10^{-4}$ for 10 g-modes periods (the tolerance window being ±0.33 μHz). We have failed to find a similar significant correspondence for $l = 1$, 2, 3 degrees of C as well as for models A and B of ref. 1.

The mean difference in the observed periods $\overline{\Delta T}$ of successive modes g_n listed in Table 1 is $\overline{\Delta T}_{obs} = 8.36 \pm 0.60$ min. According to the well known asymptotic approximation formula

$$T_{nl} = K\left(n + \frac{l}{2} - \frac{1}{4}\right)(l(l+1))^{1/2} \qquad (1)$$

and $\overline{\Delta T}_{obs}$ we have $K_{obs} = 37.4 \pm 2.7$ min ($l = 4$). On the other hand, Christensen-Dalsgaard *et al.*[1] give $K_{theor} = 37.6$ min for model C, which is in good agreement with observations, and $K_{theor} = 36.2$ min for the standard A-model. If one now compares these values with the $K = 38.6$ found recently by Delache and HScherrer[6] from a very limited set of data (one season during 1979) and for the range of periods mainly $P \geq 200$ min, one comes to the conclusion that their value (38.6 min) is appreciably nearer to our value for the C-model than to K for the standard A-model. The same is true for observations of van der Raay[7] producing the value $K \approx 41.2$ min. As all these authors deal with $l = 1$ or 2 degrees and use a standard model we can conclude that C-model values fit the observed values better than do those of the standard A-model. (However, the disagreement between Delache and Sherrer's K-value and that of van der Raay[7] is quite large, and is ≥ 10 min for periods ≥ 160 min. Difficulties with the standard model and the neccessity of using the lower abundance Z of heavy elements for p-modes ($l < 20$) has recently been pointed out by Rhodes *et al.*[8], see also ref. 9.)

The following evidence favours a deviation of the observed oscillations from linearity. (1) The observed dependence of the amplitude of oscillations on the phase of solar rotation[10] supports the fact that we also observe asymmetric dipole-like ($l = 1$) oscillations contributing to the power spectrum. (2) The recent investigation of Kosovichev and Severny[11] showed that instability really takes place for the $l = 1$ degree in the C-model (for g_1 and g_2-modes; compare with the similar conclusions of Saio[12]). (3) The amplitudes of g-modes increase towards the centre (the core) of the Sun. (4) If one compares the value of harmonic mean of the observed amplitude $\bar{a}_h = 0.67$ with the mean amplitude of bimodal terms $\bar{a}_b = (\overline{a_i a_j})^{1/2} = 0.71$ formed for the dominant peaks, one finds them quite comparable. (S. M. Ruitov, personal communication).

Therefore, because the oscillations are nonlinear, the combination frequencies $\omega_i \pm \omega_k$ can occur (see ref. 13). The corresponding combination frequencies for different peaks were also calculated and are presented in Table 1. The corresponding periods are in fairly good agreement with the observed values.

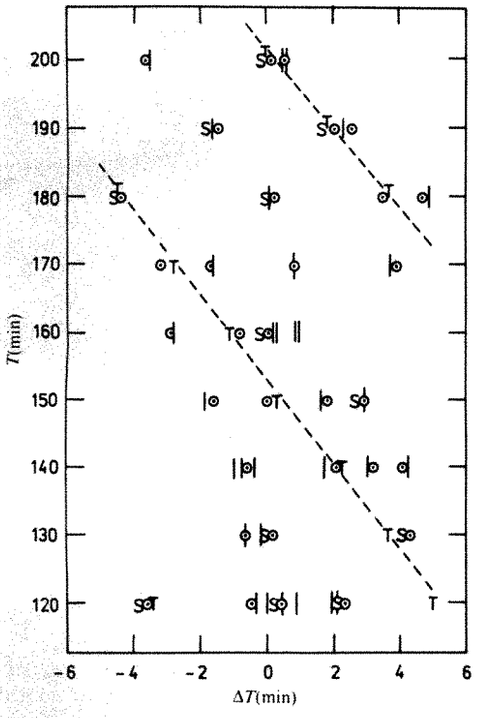

Fig. 2 Echelle-diagram of the positions of all peaks with amplitude $\geq 2\sigma$ for periods between 110 and 210 min constructed with the increment $\Delta T = 10$ min. ⊙, Solar periods; S, peaks in the Stanford spectrum coinciding with ours; T, periods of theoretical[1] 4 g_n-modes for model C and $l = 4$; 1, combination periods (see Table 1). The dashed lines show the sequences of the theoretical 4 g_n-modes.

In conclusion, let us consider 160.0-min oscillation (as well as the 120.4 and 139.4-min peaks). Besides that, at $l = 2$ the g_8 mode does exist for which the calculated value (see Table 3 in ref. 1)

$$T(2g_8) = 160.80 \quad \text{min} \tag{2}$$

and the f- and g_1-modes (the latter can be secularly unstable according to Saio[12]) form the combination mode with the period

$$[T^{-1}(2f) - T^{-1}(1g_1)]^{-1} = 160.83 \quad \text{min} \tag{3}$$

which is almost in resonance with $T(2g_8)$-mode, as $\Delta T_1 = 0.03$ min. Note that $1g_1$ and $2f$ are the lowest modes of model C. There also exists another resonance near the 160-min-period produced from the combination modes

$$\begin{aligned} [T^{-1}(2g_1) - T^{-1}(4g_6)]^{-1} &= 160.24 \quad \text{min} \\ [T^{-1}(3g_4) - T^{-1}(4g_{14})]^{-1} &= 160.21 \quad \text{min} \end{aligned} \tag{4}$$

which also have $\Delta T_2 = 0.03$ min, so that there is a 'higher'-order resonance with $\Delta T_3 = \Delta T_2 - \Delta T_1 \approx 0$ or a 'resonance of two resonances' with $\Delta T = 0.03$ min. If for model C the mode $l = 1$ is unstable (see refs 11, 12) the presence of a resonance mode (3) (and possibly $l = 2$ resonance mode (4)) can lead to a secularly unstable mode near 160.0 min. The possibility of resonance excitation of the 160-min mode was also suggested by Vandakurov[14], but this author had neither proper observational data nor theoretical modes, so that the actual condition for resonance differs from those supposed in ref. 14. The problem of resonance in other cases is now being considered separately, but it is obvious that only a very slight adjustment to model C is needed to make resonance appear precisely at the observed frequency 160.01 min. (For the possible importance of resonance coupling see also ref. 15, and ref. 16 for the instability connected with it).

A similar situation presents itself at $T = 120.4$ min (confirmed by the two Stanford peaks having the mean period 120.1 min). Here we have the secular unstable modes $l = 1$ in two combination frequencies:

$$\begin{aligned} [T^{-1}(2g_1) - T^{-1}(1g_2)]^{-1} &= 120.03 \quad \text{min} \\ [T^{-1}(3g_2) - T^{-1}(4g_{10})]^{-1} &= 120.45 \quad \text{min} \end{aligned} \tag{5}$$

also forming a very close resonance with $\Delta T_1 = 0.42$ min. There also exists a normal mode $l = 3$, g_8 with the period 120.90 min producing the difference $\Delta T_2 = 0.45$ min, so that we again have the condition $\Delta T_3 = \Delta T_2 - \Delta T_1 = 0.03$ min indicating the very close resonance conditions. We think the precise resonance at 120.4 min may mean a very slight change in model C.

We have tried to find out the near-resonance conditions for the standard A-model but have failed so far. Therefore, we have come to the conclusion that model C, which is also in much better agreement with the neutrino experiment than the other two (A and B) models of ref. 1, is a better model of the Sun, and thus the enrichment of solar atmosphere by heavy elements could be connected with the accretion process.

We thank Drs E. Fossat and P. Scherrer for permission to use their power spectra before publication, and Dr Kosovichev for helpful discussions.

Early Solar System aqueous activity: Sr isotope evidence from the Orgueil CI meteorite

J. D. Macdougall & G. W. Lugmair

Scripps Institution of Oceanography, University of California, San Diego, La Jolla, California 92093, USA

J. F. Kerridge

Institute of Geophysics and Planetary Physics, University of California, Los Angeles, Los Angeles, California 90024, USA

The CI meteorites are rare but important objects because they may represent our best sample of chemically unfractionated Solar System material (see, for example, ref. 1). Despite the fact that these meteorites apparently retain their original chemical composition, they clearly contain secondary mineral phases, some at least believed to have been produced through the action of liquid water on the parent body[2–6]. The timing of this event, however, was unknown. In an attempt to solve this problem, we have measured the Sr isotopic composition and $^{87}Rb/^{86}Sr$ in carbonates and sulphate separated from the Orgueil meteorite. Both of these phases probably precipitated from aqueous solution. Our first results, reported here, show that carbonate deposition occurred contemporaneously with parent body formation or shortly after it, probably within 100 Myr. On the other hand, at least some of the calcium sulphate seems to have been formed recently.

In the CI meteorites, the Rb/Sr ratio is high, ~0.3 (ref. 7). Thus, in low-Rb phases which contain Sr, the Sr isotopic composition should be a sensitive indicator of the time of formation,

© 1984 Macmillan Journals Ltd

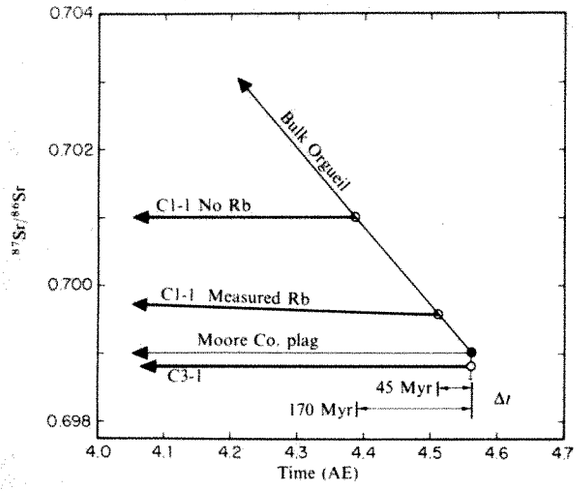

Fig. 1 An illustration of the Sr isotope method for determining the time of formation of low-Rb phases such as carbonates in the CI meteorites, using data for C1-1 (Table 1) as an example. Evolution lines are shown for the bulk meteorite ($^{87}Rb/^{86}Sr \sim 0.8$), the Moore Co. plagioclase, and sample C1-1 assuming as extreme cases that (1) the sample has no indigenous Rb and (2) the measured Rb is the true value. For purposes of calculation, no blank correction was made to the Rb data for case (2), so that $^{87}Rb/^{86}Sr = 0.022$ rather than 0.013 as reported in Table 1. This results in a lower limit for Δt (the time between 4.56 AE and the isolation of C1-1 from bulk Orgueil Sr). Also shown for comparison is the datum for C3-1, which exhibits essentially no change in $^{87}Sr/^{86}Sr$ over 4.56 AE (AE = 10^9 yr).

provided that the Sr was equilibrated with 'bulk meteorite' Sr at that time (Fig. 1). If the CI carbonates and sulphates formed during a period of aqueous activity on the parent body, they would meet this criterion. Indeed, the distribution of Ca in the Orgueil meteorite gives a clue to the behaviour of Sr. Kerridge[8] has shown that the phyllosilicates which make up 60–65% of the meteorite contain about an order of magnitude less Ca than the bulk meteorite. This suggests that most of the Ca—and by implication Sr—is concentrated in Ca-rich carbonates and sulphates.

Carbonates in the CI meteorites span a large compositional range, and sulphates occur primarily as either gypsum or hydrated magnesium sulphate. Sulphates are present as vein minerals clearly deposited along fractures, while the textural relationship between carbonates and the bulk of the meteorite is much less clear[4,6]. Richardson[6], based on a petrographic study of three CI chondrites, claimed that at least three generations of mineralization can be recognized, during which first carbonates, then Ca-sulphates and finally Mg-sulphates were deposited in veins. In the present meteorite, however, only the sulphates exist as true vein minerals; carbonates occur as single crystals or sometimes as aggregates which Richardson[6] interpreted as residual vein fragments. The most abundant carbonates are dolomite and breunnerite, the latter an Fe–Mg-carbonate. Both of these frequently contain considerable Mn[9]. Pure calcium carbonate occurs only rarely.

Sr isotopic data for carbonate and sulphate-rich samples handpicked from Orgueil are given in Table 1. Because of the expected low abundances of the elements of interest, and their susceptibility to leaching and contamination, sample processing was kept to a minimum. Bulk meteorite samples were disaggregated ultrasonically in double-distilled acetone or methanol. Light-coloured grains ≥20 μm were handpicked and grouped according to appearance. Energy-dispersive X-ray analysis using the scanning electron microscope was used to confirm the identity of phases, but because of the small sample amounts, only spot checks could be made and none of the separates is considered to be pure.

Three separate bulk meteorite samples were obtained from P. Pellas (Muséum National d'Histoire Naturelle, Paris) and

Table 1 Sr isotopic data for Orgueil carbonates and sulphates

Sample	$^{87}Sr/^{86}Sr$	Sr (p.p.m.)	$^{87}Rb/^{86}Sr$
ORG-1			
C1-1 (dolomite)	0.701007 ± 38	70	0.013
C1-2 (mixed carbonate)	0.70200 ± 10	68	0.004
ORG-2			
C2-1 (mixed)	0.70202 ± 28	17	0.44
S2-1 (Ca-sulphate)	0.76785 ± 7	87	0.023
ORG-3			
C3-1 (mixed)	0.69882 ± 20	17.1	*
C3-2 (breunnerite + matrix)	0.70522 ± 20	1.06	0.084
Moore Co. plagioclase†	0.69901		
Bulk Orgueil‡	0.75286	7.85	0.805

Sr isotopic data fractionation corrected to $^{86}Sr/^{88}Sr = 0.1194$ and relative to $^{87}Sr/^{86}Sr = 0.71025$ for NBS 987 Sr.
* Rb amount indistinguishable from blank (≤7.4 pg).
† Initial ratio based on measured value for plagioclase, $^{87}Rb/^{86}Sr$ from ref. 15, and 4.56 AE.
‡ After data in ref. 10. The Sr isotopic ratio was calculated using data from Orgueil samples 1 and 3 (ref. 10), our Moore Co. plagioclase initial ratio, and 4.56 AE.

processed as described above. The heterogeneity of the CI meteorites is emphasized by the fact that the populations of light-coloured phases in the three samples varied considerably in mineralogical makeup. In ORG-1, most of the mineral picked as carbonate was dolomite. ORG-2 and ORG-3 both contained considerably more breunnerite than dolomite, and ORG-2 contained a relatively large amount of Ca-sulphate. Each of the mineral separates for which data are reported in Table 1, except for sulphate sample S2-1, was rinsed in double-distilled water in an ultrasonic bath before dissolution; all dissolution was accomplished in 2M HCl and in all cases a small amount of undissolved residue remained. Here we discuss key points of the isotopic data and related sample properties. The details of individual samples will be described more fully elsewhere.

The data in Table 1 show a considerable range in $^{87}Sr/^{86}Sr$ for the carbonates, from 0.6988 to 0.7052. The relatively large errors result from small sample sizes, all ≤1 mg, and therefore extremely small amounts of Sr, ranging from only 32 ng down to 77 pg. The highest measured value is for Ca-sulphate S2-1, with $^{87}Sr/^{86}Sr$ greater than reported values for the bulk meteorite[10] (Table 1). However, the Rb/Sr ratio does not correlate with the Sr isotopic ratios. The lowest measured $^{87}Sr/^{86}Sr$ is for sample C3-1, overlapping within its relatively large error limits our internal initial ratio for basaltic achondrites, determined from measurements of Moore Co. plagioclase (Table 1) and an assumed age of 4.56 AE (AE = 10^9 yr). Sample C3-1 was a small mixed breunnerite + dolomite sample. After dissolution, a small amount of low-Mg breunnerite and a few small enstatite grains remained. The bulk of the dissolved material is assumed to have been dolomite + high-Mg breunnerite. Thus these phases must have been deposited very early in the history of Orgueil, perhaps essentially contemporaneously with parent body formation. The measured isotopic ratio is an upper limit because it is possible that a small amount of high $^{87}Sr/^{86}Sr$, non-carbonate Sr may have been included; nevertheless it provides an upper limit for the initial CI meteorite Sr isotopic ratio. Rb in C3-1 was indistinguishable from blank levels (≤7.4 pg). An important task will be to determine the Sr isotopic ratio more precisely, as other possible indicators of the initial $^{87}Sr/^{86}Sr$ ratio for carbonaceous chondrites come from refractory inclusions in the Allende CV3 meteorite[11,12], and may be representative of neither the bulk Allende meteorite nor carbonaceous chondrites in general. Taking inter-laboratory bias into account, the C3-1 value is consistent with the lowest values reported for Allende[11,12].

As mentioned above, other carbonate separates exhibit considerable variability in $^{87}Sr/^{86}Sr$, and the values of this ratio do not correlate with $^{87}Rb/^{86}Sr$. We do not consider model ages

Table 2 Comparison of water leach and sample data for ORG-3 separates

Sample	$^{87}Sr/^{86}Sr$	Sr (pg)	$^{87}Rb/^{86}Sr$
C3-1	0.69882±20	647	*
C3-1 leach	0.85337±37	680	0.24
C3-2	0.70522±20	77	0.084
C3-2 leach	0.80592±80	175	1.1

* Rb amount indistinguishable from blank (≤7.4 pg).

(see Fig. 1), referred to the bulk meteorite evolution, very meaningful: they range from ~4.5 AE to 9 AE using the values from Table 1. We ascribe this to the mobility of Rb in the meteorite, and the consequent difficulty of making accurate measurements of indigenous Rb in the separates, and also to the problem of 'contamination' of the carbonate separates with non-carbonate (bulk meteorite?) Sr. Even the best characterized of our separates, C3-2, which consisted of two large breunnerite crystals, contained small amounts of what appeared to be matrix material injected along cleavage planes. The isotopic data suggest that some of the less well characterized separates were more pure. It is also possible that some of the observed differences are due to real variability in the initial ratios of the carbonates, which could be caused by local (cm-scale) alteration and carbonate deposition and/or variability in the time scale of deposition. Nevertheless, the timing of deposition would have to be very close to the time of parent body formation. If no non-carbonate Rb or Sr were present in the separates for which data are given in Table 1, they must have formed within ~200 Myr of parent body formation. Even if all Rb is considered to be extraneous to the carbonates, the time scale is still relatively short—ranging from 540 Myr for sample C3-2, which in fact does contain a matrix contaminant, to 170 Myr for C1-1 and zero for C3-1.

A further important result of these initial data concerns samples C3-1 and C3-2. For both of these, Rb and Sr were measured in the 5-min ultrasonic bathwater rinse. In each case the weight loss for this leach treatment was less than several hundredths of a milligram, that is, less than a few per cent of the total sample. However, the amounts of Sr in the leach solution were about the same (C3-1) and greater than (C3-2) those in the samples (Table 2). In addition, the $^{87}Sr/^{86}Sr$ ratio in the leach solutions was very high, considerably greater than that in the bulk meteorite. As in the case of the Ca-sulphate sample, S2-1, the accompanying Rb is insufficient by a large amount to produce this ratio over the lifetime of the meteorite. Thus, there is a mobile, highly radiogenic Sr component in Orgueil not accompanied by its parent Rb. Because of its radiogenic nature, this component must be 'young'. Lacking any knowledge of the Rb–Sr history of the component, it is impossible to quantify this statement, except to say that for Rb/Sr anywhere close to the bulk meteorite, the high $^{87}Sr/^{86}Sr$ implies essentially present-day derivation. Times up to a few tens of millions of years would be permitted. The qualitative similarity of the leach and Ca-sulphate data suggests that Sr in the Ca-sulphate may have been derived recently from such a source. These results also emphasize the problem of determining the true initial ratio of the carbonate phases in the presence of such high $^{87}Sr/^{86}Sr$ components.

The data for sulphate sample S2-1 are intriguing because they suggest that the calcium sulphate was formed very recently. The timing is uncertain but would include the terrestrial age of Orgueil and the presumed breakup time of the parent body, estimated to be ~10 Myr from the cosmic ray exposure age[13,14]. Most previous workers have suggested, implicitly or explicitly, that the vein-filling sulphates and the carbonates were formed at approximately the same time, and certainly were not separated by billions of years[4,6]. Sulphate sample S2-1 was not picked directly from veins so that conceivably it is not composed of vein material; however, the platy or sheet-like habit of most of the sulphate fragments implies rather strongly that they were from fracture linings. Recent dissolution of an early sulphate generation and redeposition incorporating radiogenic Sr could also explain the data. If such an event occurred, it obviously did not greatly affect the carbonates.

These initial experiments show that the Rb–Sr system in Orgueil is complex, but that nevertheless Sr isotopes in the carbonates indicate that they were formed very early, possibly coincident with parent body formation. The lowest measured $^{87}Sr/^{86}Sr$ value among our carbonate separates is consistent with published data for the initial Sr isotopic ratio in refractory inclusions from the carbonaceous chondrite Allende[11,12]. In contrast, the Sr isotopes in a single Ca-sulphate separate suggest that this vein material formed very recently. Further experiments, now underway, will be required to unravel the complicated series of events recorded in the Sr isotopic compositions of the secondary phases of this meteorite.

We thank P. Pellas for supplying the samples for this study and M. Hitchcox for help during manuscript preparation. This work was supported by NASA grants NSG 7121 and NAG 9-49, SIO-IG²L contribution 15.

Meteoritic $^{138}Ce/^{142}Ce$ ratio and its evolution

H. Shimizu*, T. Tanaka† & A. Masuda*

* Laboratory for REE Microanalysis, Department of Chemistry, Faculty of Science, The University of Tokyo, Hongo, Tokyo 113, Japan
† Geological Survey of Japan, Higashi 1-1-3, Yatabe, Ibaraki 305, Japan

The nuclide ^{138}La decays to ^{138}Ce and ^{138}Ba by β^- and electron capture, respectively, with a total half life of about 1×10^5 Myr. Rankama[1] suggested the possibility of age determination using this radioactive decay system. Recently, Tanaka and Masuda[2] succeeded in age determination by using the ^{138}La–^{138}Ce geochronometer for a gabbro from the Bushveld complex, South Africa. This La–Ce isotopic system, coupled with the Sm–Nd system, provides a new isotope tracer[2,3] for the geo- and cosmochemical samples, especially for samples having a Ce anomaly in the rare-earth element patterns. Meteoritic primordial composition of cerium isotopes can serve as a basis for La–Ce systematics. Furthermore, Ce isotopic compositions for meteorites will provide information concerning half-life data of the ^{138}La decay system, which remains uncertain. Here, cerium isotope ratios were determined for Juvinas, Pasamonte and ALH-78132 eucrites and the Jilin (H4) chondrite. Neodymium isotope ratios and abundances of lanthanum, cerium, neodymium and samarium were also determined for these meteorites.

The experimental procedures used are almost identical to those of Tanaka and Masuda[2]. About 0.7 to 3 g of each sample was decomposed. Rare-earth elements (REE) were separated

* Uncertainties are less than 0.3%.

† Errors are 2σ mean and correspond to the last significant figures. The $^{136}Ce/^{142}Ce$ value for Johnson Matthey reagent, JMC 304, was 0.0228559 ± 0.0000011 (2σ) and the $^{143}Nd/^{144}Nd$ value for La Jolla Nd isotope standard was 0.51183 ± 0.00003 (2σ). The average value (±s.d.) of the meteoritic $^{136}Ce/^{142}Ce$ ratio was calculated by the following equation: $\bar{x} \pm \sigma = [\sum(x_i/\sigma_i^2)/\sum(1/\sigma_i^2)] \pm \sqrt{[\sum(x_i - \bar{x})^2/\sigma_i^2]/(n-1)\sum(1/\sigma_i^2)}$.

‡ The values are estimated for 4.56×10^3 Myr ago, by assuming $\lambda_\beta\ ^{138}La = 2.58 \times 10^{-12}\ yr^{-1}$ and $\lambda_{EC}\ ^{138}La = 4.59 \times 10^{-12}\ yr^{-1}$.

from the major elements by an AG50W-X8 resin column in HCl media, while Ce and Nd were separated using an AG50W-X8 resin column with α-hydroxy-isobutyric acid. Ce and Nd isotopic compositions were measured on a semi-automatic Micromass 54R and abundances of La, Ce, Nd and Sm were determined on a JEOL JMS-05RB mass spectrometer. Cerium isotopes (about 5 μg Ce loaded) were measured as CeO^+ using Re triple filaments and the observed $^{138}Ce/^{142}Ce$ were normalized to $^{136}Ce/^{142}Ce = 0.01720$. The neodymium ion was measured as NdO^+ using a Re single filament and the measured isotope ratios were normalized against $^{146}Nd/^{144}Nd = 0.7219$.

Table 1 shows the results of Ce and Nd isotopic ratios as well as $^{138}La/^{142}Ce$ and $^{147}Sm/^{144}Nd$ ratios. The $^{138}Ce/^{142}Ce$ ratios for Juvinas and Pasamonte eucrites and the Jilin chondrite are between 0.0228518 and 0.0228538. An average value of the present $^{138}Ce/^{142}Ce$ ratios for these meteorites is 0.0228527 ± 0.0000009 (2σ). Furthermore, the average value of the $^{138}La/^{142}Ce$ ratios for these meteorites is 0.00306 ± 0.00005 (2σ). This value corresponds to 0.378 of the La/Ce abundance ratio. Here, we evaluate the primordial $^{138}Ce/^{142}Ce$ ratio for these three meteorites by assuming $T = 4.56 \times 10^3$ Myr, $\lambda_\beta\ ^{138}La = 2.58 \times 10^{-12}\ yr^{-1}$ and $\lambda_{EC}\ ^{138}La = 4.59 \times 10^{-12}\ yr^{-1}$ (ref. 2), and by using the present observed values for the La/Ce abundance ratios. The calculated primordial values of $^{138}Ce/^{142}Ce$ are 0.0228174 and 0.0228147 for the Jilin chondrite, 0.0228149 for the Pasamonte eucrite and 0.0228174 for the Juvinas eucrite. The average value of these four calculated ratios for primordial $^{138}Ce/^{142}Ce$ is 0.0228162 ± 0.0000014 (2σ). Tanaka and Masuda[2] estimated primordial $^{138}Ce/^{142}Ce$ to be 0.022816. An error in the calculation of primordial $^{138}Ce/^{142}Ce$ ratio for each meteorite in Table 1 involves the errors in the isotope and concentration determination. In this calculation, the error in the La/Ce abundance ratio is estimated to be 0.3%. In the calculation, a variation of 0.3% in the $^{138}La/^{142}Ce$ value yields only a minor change of 0.0000001 in the primordial $^{138}Ce/^{142}Ce$ value. The primordial value (0.0228162) obtained from the Ce isotope ratios of meteorites will be of great significance as a reference for Ce isotope systematics.

The Antarctic eucrites display a heterogeneous distribution of Ce anomaly[4]. Samples ALH-78132,71 and ALH-78132,79 are from the outermost part of the ALH-78132 Antarctic eucrite and they show a positive Ce anomaly. ALH-78132,78 is a chip from the inner part of the same eucrite (several centimetres inside the ALH-78132,79 sample) and this ALH-78132,78 sample possesses a negative Ce anomaly. The observed $^{138}Ce/^{142}Ce$ ratios are 0.0228489 ± 0.0000022 (2σ) for ALH-78132,71, 0.0228525 ± 0.0000062 for ALH-78132,79 and 0.0228547 ± 0.0000118 for ALH-78132,78. Based on the primordial value for $^{138}Ce/^{142}Ce$, and assuming that the present observed values for the La/Ce abundance ratio are valid for 4.56×10^3 Myr, except for the change due to radioactive decay, one is led to the result that the present $^{138}Ce/^{142}Ce$ ratios should be 0.0228442 ± 0.0000015 for ALH-78132,71, 0.0228437 ± 0.0000015 for ALH-78132,79 and 0.0228597 ± 0.0000015 for ALH-78132,78. Comparing the observed $^{138}Ce/^{142}Ce$ ratios of ALH-78132 with the corresponding values of other meteorites and calculated $^{138}Ce/^{142}Ce$ ratios for ALH-78132, we conclude that the positive Ce anomaly observed in ALH-78132,71 and ALH-78132,79 was not produced 4.56×10^3 Myr ago. This conclusion suggests strongly that the positive Ce anomaly in question was produced by terrestrial weathering. The observed $^{138}Ce/^{142}Ce$ ratio of ALH-78132,78 is somewhat lower than the calculated ratio, but the precision in isotope ratio determination for this sample was relatively poor. Therefore, more precise determination of Ce isotope abundance will be needed before we know whether the negative Ce anomaly for ALH-78132,78 was produced by terrestrial weathering.

We thank Dr H. Mabuchi and Dr B. Mason for offering Juvinas and Pasamonte eucrites, respectively, also the National Institute of Polar Research, Japan for offering the Antarctic eucrite.

Carbon isotope composition of low molecular weight hydrocarbons and monocarboxylic acids from Murchison meteorite

George Yuen*, Neal Blair†‡, David J. Des Marais† & Sherwood Chang†

* Center for Meteorite Studies, Department of Chemistry, Arizona State University, Tempe, Arizona 85287, USA
† NASA Ames Research Center, Moffett Field, California 94035, USA
‡ Department of Chemistry, Stanford University, Stanford, California 94301, USA

The origin of the organic matter in carbonaceous meteorites remains controversial despite extensive study[1–4] over the past 20 yr. Motivated by the expectation that the patterns of isotopic variation with molecular structure among the organic compounds would contain important clues to their origin, we have measured the carbon isotopic compositions for individual hydrocarbons and monocarboxylic acids from Murchison meteorite, a C2 carbonaceous chondrite which fell in Australia in 1969. With few exceptions, notably benzene, the volatile products are substantially isotopically heavier than their terrestrial counterparts, signifying their extraterrestrial origin. For both classes of compounds, the ratio of ^{13}C to ^{12}C decreases with increasing carbon number in a roughly parallel manner,

0028–0836/84/030252—03$01.00

and each carboxylic acid exhibits a higher isotopic ratio than the hydrocarbon containing the same number of carbon atoms. These trends are consistent with the kinetically controlled synthesis of higher homologues from lower ones[5,6]. The results suggest the possibility that the production mechanisms for hydrocarbons and carboxylic acids may be similar; they also impose constraints on the identity of the reactant species.

Identifications and abundances of individual hydrocarbons[7,8], monocarboxylic acids[9,10], and amino acids[11–20] have been reported, but these data have not identified clearly either the source regions or the production mechanisms for these compounds. Large differences in carbon isotopic composition between carbonate and acid insoluble organic matter have been interpreted as evidence for a Fischer–Tropsch synthesis for all the carbonaceous matter from CO, H_2 and NH_3 in the solar nebula[21,22]. However, recent measurements of the nitrogen[23–25], carbon[3,24–26] and hydrogen[24–27] isotopic compositions of the organic matter question rather than support this simple interpretation. In a summary of the only previous attempt to measure the isotopic composition of individual compounds, a range of values was reported collectively for an amino acid fraction[26].

In a closed, evacuated 700-ml Pyrex apparatus, three interior pieces (23.5 g) of Murchison meteorite were disaggregated by 40 freeze–thaw cycles in water (50 ml) assisted by sonication. After a 20-ml aliquot of the head space gas was removed for analysis of the predominant constituent, carbon dioxide, (Table 1), the remaining head space gases were cryogenically transferred, along with several millilitres of water, to a KOH trap cooled with liquid nitrogen, while the freeze–thaw apparatus was maintained at 40 °C by a water bath. Normally, methane and carbon monoxide are non-condensable at liquid nitrogen temperature, but they become condensable at that temperature in the presence of water, probably by clathrate formation[8]. The gases in the KOH trap were released by warming and introduced into a gas chromatograph–combustion (GCC) system[28,29], which separated and combusted each component to carbon dioxide for isotopic analysis. The ^{13}C abundances of hydrocarbon standards processed through the isolation–combustion procedure differed by no more than 0–0.2‰ from those of unprocessed standards. Ethane was the worst case in that it was 0.2‰ enriched in ^{13}C relative to the unprocessed standard. The recoveries of standards were 94–100% with butene having the poorest at 94%. Apparently, little, if any, sample loss or isotopic fractionation occurred during the overall analytical procedure. Abundances and carbon isotope values for the individual hydrocarbons thus obtained from Murchison meteorite are listed in Table 1.

For the analyses of the carboxylic acids, the solution in the freeze–thaw apparatus was separated from the meteorite solid, neutralized with KOH, and dried by rotary evaporation. The resulting residue was redissolved in water, acidified with H_3PO_4 and distilled. The volatile carboxylic acids in the distillate were separated by ion suppression chromatography and combusted to CO_2 in the GCC system. The isotopic compositions of two known carboxylic acids, acetic and propionic acid, were in good agreement (<0.7‰) before and after processing through the analytical procedure. The abundances and isotopic compositions of the water soluble carboxylic acids in Murchison meteorite are given in Table 1.

The abundances of carboxylic acids and saturated hydrocarbons decrease with increasing carbon number, and acids are more abundant than hydrocarbons of the same carbon number by factors of 10 (C_5) to 100 (C_2). The carbon in the acids is systematically heavier isotopically than that in the hydrocarbons. Generally, for both classes of compounds, increasing carbon number is also associated with decreasing ^{13}C-abundance, and branched isomers are isotopically heavier than their normal (straight-chained) counterparts. The isotopic compositions of the saturated members of each class are plotted against carbon number in Fig. 1, with CO_2 taken as the C_1-acid counterpart to CH_4 and assuming −7.9‰ (Table 1) to be representative of pentane. Except for the deviation by butane, two roughly parallel curves result for the normal isomers.

Table 1 Abundance and isotopic composition of hydrocarbons* and monocarboxylic acids† in Murchison meteorite

Compound	Abundance (nmol g^{-1})	$\delta\,^{13}C_{PDB}$
Carbon dioxide	2.4×10^3	+29.1 ± 0.2
Carbon monoxide	2.1	−32 ± 2
Methane	8.9	+9.2 ± 1.0
Ethane	8.5	+3.7 ± 0.1
Propane	8.9	+1.2 ± 0.1
Isobutane	4.3	+4.4 ± 0.1
Butane	5.5	+2.4 ± 0.1
Pentane	‡	
Ethene	1.3	−0.1 ± 0.4
Butenes	‡	
Benzene	28	−28.7 ± 0.2
Acetic acid	1.70×10^3	+22.7 ± 0.2
Propionic acid	6.2×10^2	+17.4 ± 0.2
Isobutyric acid	2.5×10^2	+16.9 ± 0.2
Butyric acid	1.8×10^2	+11.0 ± 0.3
Isovaleric acid	1.0×10^2	+8.0 ± 0.2
Valeric acid	47	+4.5 ± 0.2

* The gas mixture was transferred to a KOH trap at liquid nitrogen temperature. To separate these volatile gases for GCC analysis, the gases from the KOH trap were passed through a trap at dry ice–acetone temperature (water removal) on the way to the GCC sample loop (liquid nitrogen temperature), where the condensable gases collected and the noncondensable gases (mostly methane and carbon monoxide) flowed through to a collection trap with the aid of a Toepler pump. Except for CH_4 and CO, separation of the hydrocarbons on the GCC system was achieved on a Porasil B column. Chromatographic conditions: thermal conductivity detector, stainless steel column (2.5 m × 0.3 cm internal diameter) packed with Porasil B 100/150 mesh. Initial oven temperature, 28 °C, initial time 16 min; temperature programmed at 6 °C min^{-1} from 28 to 200 °C; flow rate 15 ml min^{-1}. Methane and carbon monoxide were separated on a stainless steel chromatographic column (1 m × 0.3 cm internal diameter) packed with molecular sieve 5A, 100/120 mesh, column temperature, 60 °C, flow rate 15 ml min^{-1}.

† The aqueous acid extract was brought to *p*H 10 with 2.7 M NaOH and dried by rotary evaporation. The sodium salts were dissolved in 5 ml H_2O, acidified to *p*H 2 with H_3PO_4 and distilled cryogenically. The distillate was brought to *p*H 10 and dried at 100 °C. The resulting residue was taken up in 200 μl of 1 M H_2SO_4 and chromatographed on a Hewlett-Packard 1084B liquid chromatograph, equipped with an Alltech RP-8 column (25 cm × 4.6 mm). A gradient of 100% 0.01 M H_2SO_4 going to 85% 0.01 M H_2SO_4 and 15% MeOH was used to separate the acids. The butyric and valeric acids (*n*- and iso-) were collected as two groups. The collected fractions were neutralized with NaOH and dried at 100 °C. Each sample was dissolved in 100 μl of H_2O and 50 μl of H_3PO_4 and cryogenically distilled for GCC. The acids are then separated and combusted to CO_2. Gas chromatographic conditions: stainless steel column (2 m × 0.3 cm internal diameter) packed with 10% Alltech AT 1000 on Gas Chrom A 60–80 mesh, oven temperature 140 °C, flow rate 15 ml min^{-1}.

‡ Analysed together, 1.2×10^{-2} μmol g^{-1}, −7.9 ± 0.05‰.

Although these data alone do not give clear indications of the origin(s) of the hydrocarbons and acids, some general conclusions about the required extraterrestrial processes are warranted. Both classes of compounds are products of kinetically controlled processes. That the abundances of the individual hydrocarbons in the suite are approximately of the same magnitude contradicts relative abundances expected of a thermodynamically controlled process. Calculations carried out for sets of temperature, pressure, and H to C to O elemental ratios that approximate possible solar nebular and planetary conditions[30] yielded relative abundances for methane, ethane, and benzene that vary typically by factors exceeding 10^5. The observed variations shown in Table 1 are even smaller than those reported by Des Marais *et al.*[31] for a similar suite of hydrocarbons in natural gas samples whose kinetically controlled relative abundances differed typically by $<10^3$. A similar conclusion regarding the role of thermodynamic equilibrium is applicable to the carboxylic acid abundances[30,32].

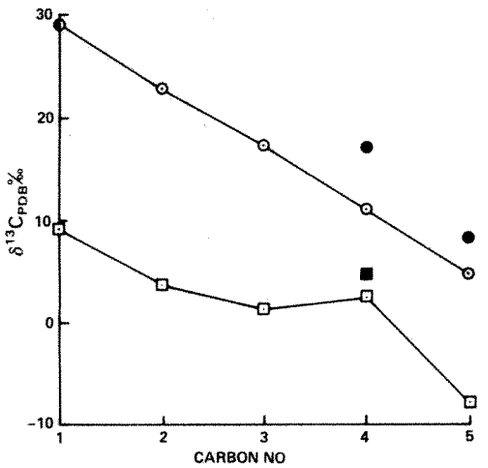

Fig. 1 Plots of $\delta\ ^{13}C_{PDB}$ values of individual saturated hydrocarbons (⊡) and carboxylic acids (⊙) against carbon number. For example, 1 denotes methane or CO_2 (○), 2 ethane or acetic acid and so forth. Values for branched isomers are indicated by filled symbols.

The variation of isotopic composition with carbon number is consistent with formation of higher molecular weight species from lower homologues. Chang *et al.*[6] and Des Marais *et al.*[5] demonstrated that the ratio of ^{13}C to ^{12}C in hydrocarbons synthesized from methane are lower than that of the reactant, decreasing monotonically with increasing carbon number. This pattern follows from the fact that in kinetically controlled synthesis a reactant containing ^{12}C typically reacts more rapidly than its counterpart containing ^{13}C. The trend towards isotopically lighter carbon with increasing carbon number is apparent for both classes of compounds in the data of Table 1. The roughly parallel isotopic variation between both classes implies that some aspects of their histories are similar. The isotopic data also indicate that the carbon monoxide and acid insoluble carbon (both isotopically light, $<-10‰$) are unlikely to have supplied the source carbon for most, if not all, the compounds analysed. No processes have been reported that yield organic compounds in which the carbon is isotopically heavier than that of the starting material. Multiple production mechanisms are not excluded by the data, however. Work in progress is aimed at elucidating the possible connection between CO_2 and the hydrocarbons in the synthesis of the carboxylic acids by determining the intramolecular isotopic composition of the volatile acids.

In principle these compounds in carbonaceous meteorites may have been synthesized in interstellar clouds, the pre-solar nebula or parent bodies (or some combination)[3,4,23–27,32]. This uncertainty in origin may be diminished as more systematic study is directed at determining the variations of C, N, H-isotopic composition with chemical structure in the organic constituents of meteorites, on the one hand, and in the organic compounds produced by model processes, on the other. When the patterns of isotopic variation with chemical structure in the natural and synthetic products are compared, similarities may come to light that are diagnostic of common production mechanisms and are therefore attributable to specific source regions.

We thank the Smithsonian for meteorite specimens 5455. G.Y. was supported by an NRC–NASA fellowship and by NASA NSG-7255.

Stable isotope compositions of gases and vegetation near naturally burning coal

Jim D. Gleason & T. Kurtis Kyser*

US Geological Survey, MS 963, Denver Federal Center, Denver, Colorado 80225, USA

Our measurements of stable isotope compositions of CO_2 issuing from vents produced by naturally burning coal indicate that the coal is oxidized through a kinetic process in which groundwater is the oxidizing agent. The CO_2 produced by the oxidation of the coal is extremely depleted in ^{13}C relative to normal atmospheric CO_2. The change in the $\delta^{13}C$ value of atmospheric CO_2 near the vents resulting from the burning coal was not recorded in tree rings from red cedars, but the $\delta^{13}C$ values of some C_3 and C_4 type plants collected from within the area were greatly affected. Our results indicate that the $\delta^{13}C$ values of some species of plants may be sensitive indicators of changes in the carbon isotopic composition of atmospheric CO_2.

Although the photosynthetic pathway of a plant appears to be the primary factor that determines its carbon isotope ratio[1,2], the range in the carbon isotopic composition of plants having the same pathway must be due to other factors. Mazany *et al.*[3] suggested that variations in the $^{13}C/^{12}C$ ratios of tree rings from the same tree were due to past changes in climate, and that the two species of trees they studied must have had different responses to these climatic changes. Sternberg and DeNiro[4] measured a range of nearly 5‰ in the $^{13}C/^{12}C$ ratios of cellulose of C_3 plants collected from the same area and they ascribed this range to differences among the biological factors of the plants. Inasmuch as the $^{13}C/^{12}C$ ratios measured by Sternberg and DeNiro[4] were different for the cellulose from plants collected from the same area and having the same photosynthetic pathway and physiognomy, the biological factors must be as species-dependent as the climatic factors.

To understand better the response of different species of plants to changes in the $^{13}C/^{12}C$ ratio of atmospheric CO_2 due to the burning of fossil fuels, we have measured the stable isotopic composition of herbaceous plants and trees surrounding vents produced by naturally burning coal as well as of the gases emanating from these vents. Carbon isotope ratios of plants surrounding burning coal vents should be sensitive indicators of

Nature Author Indexes

Nature Author Indexes are published bimonthly. Indexes for the previous 1983 volumes were published in the issues of 17 March (Vol.301), 10 May (Vol.302), 21 July (Vol.303), 15 September (Vol.304) and 24 November (Vol.305).

AN 'RT' THAT WORKS NEEDN'T BE AN 'ET' ONE

nature is keeping ahead. Are you being left behind?

New research results, the very latest international science news, key papers by the world's leading scientists and speed of publication ensure *Nature* remains one of the foremost weekly scientific journals in the world.

But if you're tied in to a circulation list at work, all this vital weekly information will undoubtedly reach you late, often incomplete and sometimes not at all.

With your own personal copy, you solve the problem. Every week you'll have all the latest research results and science news in your hands within days of publication:

News reports from throughout the world of science and technology.

A **News and Views** section, where new ideas are analysed and discussed by leading researchers.

Articles and Letters in which key investigators disclose their work for the first time.

Book Reviews – Eminent figures offer expert judgments on a wide variety of recent publications.

Special Issues providing an in-depth treatment of topics of importance.

Product Reviews – Detailed descriptions of laboratory equipment newly available.

Classified Advertisements for a wide variety of positions all over the world.

You will no longer be dependent upon other people passing down the 'list' copy, and because you will automatically receive every issue, you won't risk missing a single copy through absence from work. Moreover, you keep all this key information for permanent reference.

Through your door every week

Subscribe now – at Half Price

Become a personal subscriber now and you will receive a discount of 50% off the full rate.

All 51 weekly issues will be delivered to the address of your choice. You can start your annual subscription with any issue you choose. And you will receive six bi-monthly author indexes, together with the annual index of subject and author.

All this for just 94p a week.

Place your order now and make certain that you receive the scientific news and research results crucial to your work when you want them.

☐ I accept: Please send me a personal subscription to *Nature* for one year (51 issues) at the special half-price rate of £49.00.

☐ I enclose my personal cheque for £49.00 made payable to *Nature*. (Note: Institutional cheques cannot be accepted at this special rate).

☐ Please charge to my credit card account.

This offer applies to UK and North America only. Please allow approximately 4 weeks for delivery of the first issue in your subscription year.

nature

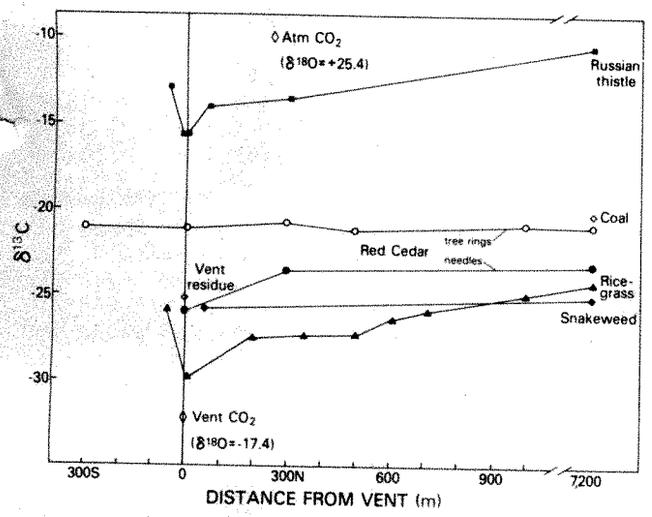

Fig. 1 Variations in $\delta^{13}C$ values of various materials as a function of their proximity to the vent. CO_2 issuing from the vent has a $\delta^{13}C$ value of −32.0 and a $\delta^{18}O$ value of −17.4, whereas atmospheric CO_2 300 m north of the vent has a $\delta^{13}C$ value of −10.3 and a $\delta^{18}O$ value of +25.4. Residue collected inside the vent has a $\delta^{13}C$ value of −25.0, and coal samples collected away from the vent area at two separate sites have identical $\delta^{13}C$ values of −21.0. Wood from tree rings of red cedar exhibits no isotopic effects from burning coal contamination, whereas needles of a red cedar on the vent trend do show some contamination. Roots from Russian thistle (a C_4 plant), stems from ricegrass, and roots from snakeweed (both C_3 plants) exhibit decreasing contamination in their $\delta^{13}C$ values as a function of their distance north of vents (prevailing wind is from the south). The plants collected south of the vent exhibit very little contamination from the vent gas in their $\delta^{13}C$ values.

Table 1 Stable isotope compositions of materials and gases associated with naturally burning coal

Sample	Location	$\delta^{13}C$	$\delta^{18}O$
Coal	Bed 1*	−21.0	
Coal	Bed 2*	−21.0	
CO_2	Large vent	−32.5	−17.4
CO_2	Atmosphere 300 m north of vents	−10.3	+25.4
Carbonaceous material	Wall of large vent	−25.1	

* Coal beds 1 and 2 are two separate veins collected south of the vent trend from an area where there was no evidence of burning.

the response of different species to local effects of fossil fuel burning because the CO_2 produced from the combustion of coal should be extremely depleted in ^{13}C relative to normal atmospheric CO_2. In addition, stable isotope ratios of the gases emanating from the vents may provide information on the mechanisms by which coal burns naturally.

Carbon isotope ratios of organic material were determined using carbon dioxide gas that was produced by the complete combustion of the organic material at 800–1,000 °C in purified oxygen at 1 atmosphere. The carbon dioxide was purified and then analysed in a 6″–60° sector isotope ratio mass spectrometer. Before combustion, the wood samples were chopped in a Wiley mill, then extracted with benzene and ethanol in a Soxhlet extractor to remove soluble components. The resulting sample was composed primarily of cellulose and lignin. Differences between the $^{13}C/^{12}C$ ratios of wood treated in this manner and untreated wood were small (<0.2‰). The wood samples were collected from tree rings representing the past 20 yr of growth. The height of the trees was 1–2 m. Plant samples were dried and combusted directly, without any chemical treatment. The herbaceous plants were all ~0.5–1 m in height. Atmospheric and vent gases were collected in evacuated stainless steel cylinders and CO_2 was separated and purified by differential freezing

techniques. The results are reported in units of ‰ relative to SMOW standard for oxygen or relative to PDB standard for carbon and are accurate to ±0.2‰ based on replicate analysis. The $\delta^{13}C$ value of NBS-21 in this laboratory is −28.1 relative to PDB.

The burning coal beds are part of the Straight Cliffs Formation located at 37°17′30′ N, 111°22′ W in the Escalante Quadrangle near the Utah–Arizona border. This formation consists of interbedded, Upper Cretaceous marine and nonmarine sandstones, mudstones, shales and coal[5]. Areas where coal is burning or has burned are easily recognized because the sandstones, which are usually yellow, are turned red by the heat and gases from the burning coal. The collection site is located on the southern edge of the arid Kaiparowits Plateau in the Smoky Mountains. A 200-m long, east–west-trending series of small vents each ~4 cm in diameter, breach the red sandstone surface of this area. Two large vents (1–2 m in diameter) on the western edge of this trend are the most active and, therefore, served as the focus of the study. The local topography was such than the vents were ~2 m higher in elevation than the surrounding area. Approximately 10 l min^{-1} of steam and carbonaceous gases issue from each of the large vents. The gas collected from the vents consists of ~70% air, 7% steam, 20% CO_2, 2% CH_4 and 1% saturated hydrocarbons. These gases are blown northwards by prevailing winds.

Coal from different beds in this area have $\delta^{13}C$ values near −21.0 (Table 1, Fig. 1). Carbonaceous material which precipitated on the walls of the vents has a lighter value of −25.1 and CO_2 from the vent is even lighter at −32.5 (Table 1, Fig. 1). Modern atmospheric CO_2 normally has $\delta^{13}C$ values between −7.5 and 8.0 (ref. 6 and I. Friedman and J.D.G., in preparation), so that the CO_2 issuing from the vent is not atmospheric but is derived from the oxidation of the coal. Furthermore, equilibrium fractionation factors indicate that ^{13}C is always concentrated in

Table 3 Calculated carbon isotope fractionations between certain plant species and atmospheric CO_2

Ricegrass	*Oryzopsis webberi*	Stem	−17
Russian thistle	*Salsola kali*	Root	−3

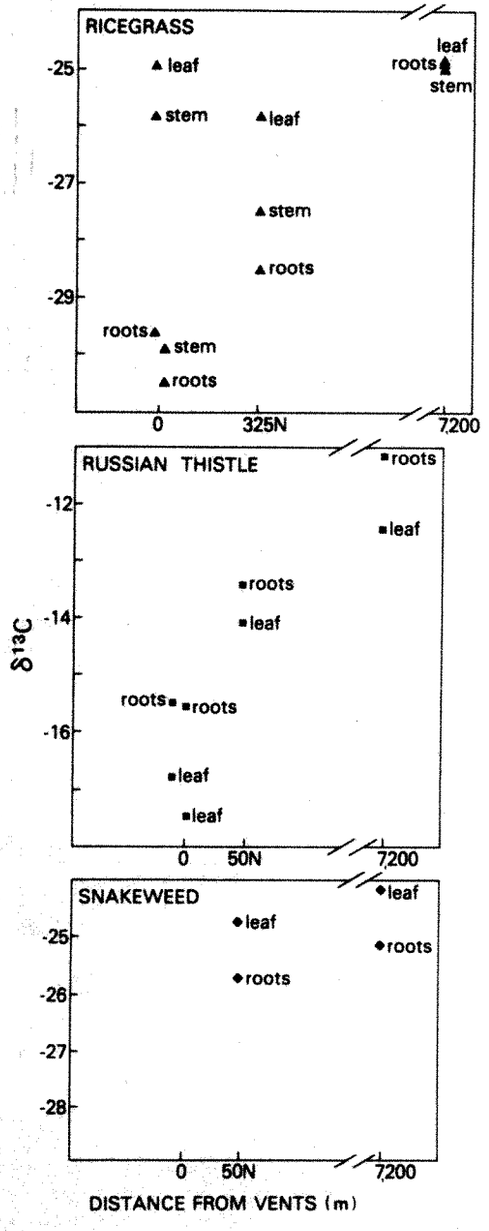

Fig. 2 $\delta^{13}C$ values of various parts of plants as a function of their proximity to the vents. Snakeweed and ricegrass, both C_3 plants, have more negative $\delta^{13}C$ values in their roots than in their leaves or stems, whereas Russian thistle, a C_4 plant, shows the inverse trend. Although the difference between the $\delta^{13}C$ values of roots and leaves from Russian thistle is constant, those plants growing near the vents have $\delta^{13}C$ values which indicate that they have incorporated vent CO_2 during photosynthesis. Ricegrass exhibits large variations among the $\delta^{13}C$ values of various organs of plants collected in areas where there is contamination from vent CO_2, and very little variation in organs from plants collected from the control area. The roots of ricegrass collected south of the vent (prevailing wind is from the south) exhibit contamination by vent CO_2, whereas the leaf and stem do not.

CO_2 relative to a reduced-carbon phase even at high temperatures[7] so that the CO_2 from the vent is not in isotopic equilibrium with either the carbon in the coal or the carbonaceous material from the walls of the vent. Instead, the isotope data indicate that the coal burns by a kinetic process wherein ^{12}C in the coal is preferentially oxidized relative to ^{13}C.

The oxygen isotopic composition of the vent CO_2 is −17.4 (Table 1, Fig. 1), a value only moderately more ^{18}O-depleted than the isotopic composition of −15 for groundwater that would be expected from this area[8]. Atmospheric O_2 has a $\delta^{18}O$ value of +23.5 (ref. 9). The extreme ^{18}O depletion of the vent CO_2 relative to that expected from the kinetic oxidation of the coal by atmospheric O_2 leads us to conclude that the source of most of the oxygen in the naturally burning coal must come from a reservoir having a low $\delta^{18}O$ value such as that of the groundwater.

Red cedars (*Juniperus scopulorum* Sarg.) were collected with the anticipation that the ^{13}C-depleted CO_2 issuing from vents would produce wood having low $\sigma^{13}C$ values. The $\delta^{13}C$ values of wood from trees 5 and 10 m north of the vents were identical to the values of control trees >7.2 km away (Table 2, Fig. 1). Evidence that the red cedars were exposed to the vent CO_2 is observed in the $\delta^{13}C$ values of some of the needles of a cedar located 10 m north of the main vent (Fig. 1). These were depleted in $\delta^{13}C$ by 2‰ relative to needles from trees further from the vents, suggesting that they may be more sensitive indicators of local isotopic anomalies than are the tree rings. The absence of low $\delta^{13}C$ values of the tree rings from samples collected near the vents suggests that the fractionation of carbon isotopes between red cedars and atmospheric CO_2 is not always constant.

Unlike the red cedars, the isotopic compositions of certain herbaceous plants were affected by the CO_2 issuing from the burning coal vents (Table 2, Fig. 1). The effect was observed in the carbon isotopic compositions of plants using each of the two common pathways of photosynthesis and in plants with different physiognomies. For example, the $\delta^{13}C$ values of samples of Russian thistle, a herbaceous annual C_3 plant, and ricegrass, a C_4 plant, are both strongly dependent on their position relative to the vents. Samples of snakeweed, a woody perennial C_3 plant, have $\delta^{13}C$ values which are less dependent on their position relative to the vents.

Although different organs of each plant have different carbon isotopic compositions because of variations in their chemical components[10], the $^{13}C/^{12}C$ ratio of the vent CO_2 is reflected in the $\delta^{13}C$ values of all the organs in plants collected near the vents (Fig. 2). Differences among the $\delta^{13}C$ values of the organs of snakeweed and Russian thistle are constant although organs of these plants closest to the vents are depleted in ^{13}C relative to corresponding organs of the control plant. However, the difference between the roots of snakewood collected 50 m north of the vents is depleted in ^{13}C by only 0.5‰ relative to the roots of the control plant whereas the roots of Russian thistle 50 m north of the vents is depleted by 2.5‰ relative to the control plant. Differences among the $\delta^{13}C$ values of various organs of ricegrass are not constant: the roots and stems have more variable $\delta^{13}C$ values than do the leaves.

Russian thistle and ricegrass appear to be the species most sensitive to changes in the isotopic composition of local atmospheric CO_2. With a $\delta^{13}C$ value of atmospheric CO_2 of −8.0 surrounding the control plants, the fractionation factor between the roots of Russian thistle (C_3 plant) and CO_2 is −3.0 whereas the fractionation factor between the stems of ricegrass (C_4 plant) and CO_2 is −16.8. Atmospheric CO_2 collected 300 m north of the vents above the zone that may have been affected by CO_2 from the local flora and fauna has a $\delta^{13}C$ value of −10.3 (Table 1, Fig. 1). The fractionation factor between roots of Russian thistle collected 300 m north of the vents and the local atmospheric CO_2 having a $\delta^{13}C$ of −10.3 is −2.8 whereas the corresponding factor between the stems of the ricegrass 325 m north of the vent and this CO_2 is −17.2. Although the fractionation factors for these two species differ greatly, the fractionation

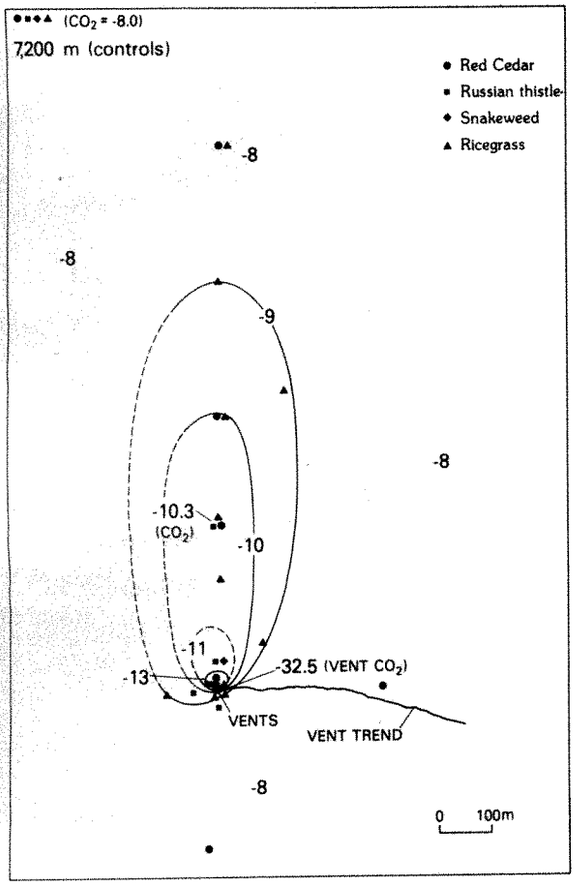

Fig. 3 Estimated $\delta^{13}C$ contours of local atmospheric CO_2 in the area surrounding the vents. From a $\delta^{13}C$ value of −8.0 for CO_2 in equilibrium with the roots of Russian thistle and stems of ricegrass from the control area and a value of −10.3 for atmospheric CO_2 in equilibrium with these plants collected 300 m north of the vents, the fractionation of $\delta^{13}C$ between the organs of these plants and atmospheric CO_2 was calculated (Table 3). By applying these calculated isotope fractionations to the $\delta^{13}C$ values measured in plants collected from the area surrounding the vents, contours can be drawn showing average $\delta^{13}C$ values of atmospheric CO_2. The $\delta^{13}C$ values of −32.5 for vent CO_2 and −10.3 for atmospheric CO_2 collected 300 m north of the vents are also shown.

factors between the control plants and local CO_2 are similar to those of plants of the same species under the influence of ^{13}C-depleted CO_2 from the vents. This suggests that the $\delta^{13}C$ values of Russian thistle and ricegrass reflect the isotopic composition of the local atmospheric CO_2.

Because the $\delta^{13}C$ values of tissues of Russian thistle and ricegrass depend on the $\delta^{13}C$ value of atmospheric CO_2 surrounding the plants during photosynthesis, it should conversely be true that the $\delta^{13}C$ value of atmospheric CO_2 can be determined from the $\delta^{13}C$ value of the plant. By using the fractionation factors listed in Table 3 and the $\delta^{13}C$ values of the plants from the area around the vents, $\delta^{13}C$ contours of atmospheric CO_2 surrounding the vents have been estimated (Fig. 3). Contamination effects of the vent CO_2 on the isotopic composition of the plants are detected up to a distance of 1 km to the north.

The burning coal area located in the Escalante Quadrangle near the Utah–Arizona border is a natural laboratory for studying the effects of the burning of fossil fuels on the atmosphere and on the biosphere. Our results suggest that: (1) the source of most of the oxygen in gases from naturally burning coal may be from a low $\delta^{18}O$ reservoir such as groundwater; (2) wood from tree rings does not necessarily record small variations in the $\delta^{13}C$ values of atmospheric CO_2; and (3) some C_4 and C_3 plants do record small variations in the value of atmospheric CO_2 so that by analysing the $\delta^{13}C$ value of selected organs of some carefully chosen plants, the extent of any contamination to normal atmospheric CO_2 can be estimated.

Persistence of organic phosphates in buried soils

J. H. Ottaway

Biochemistry Department, Edinburgh University Medical School, Edinburgh EH8 9XD, UK

Studies of the occurrence of phosphate in soil on archaeological sites have sometimes measured total phosphate[1], but more frequently the inorganic or 'available' phosphate[2,3]—that extractable by brief treatment with acid or by inorganic solutions in the cold. The nature of the organic phosphate component does not seem to have been examined. Here we present an analysis of total phosphate and inorganic phosphate in 50 samples of soil taken from various levels of a site with a continuous settlement record from 1,600 to 6,800 yr BP. We could detect no mineralization of organic phosphate, at least over the period 1,600–5,200 yr BP. But in the upper soils, corresponding to the interval 1600–2800 BP, there was much more organic phosphate than in the lower samples, the transition being quite sharp. We tentatively conclude that the lower soils belonged to an island site relatively sparsely inhabited and often covered with natural vegetation. The upper soils corresponded to a more dense settlement in which organic phosphate, possibly phytic acid, was deposited on the transient surface and was not incorporated into the soil phosphate cycle.

Three groups of workers have compared the proportions of organic and inorganic phosphate in soil buried beneath an ancient structure: a Roman villa in England[4] (~1,800 yr BP), a megalithic tomb in Ireland[5], (~4,000 yr BP), and a Kurgan burial mound in Moldavia[6] (~4,500 yr BP). In each instance the findings were essentially similar. When the phosphate content of soil layers just below the present-day soil surface were compared with equivalent layers below the buried structure (a layer 25–50 cm below the surface was used for comparison in order to eliminate any phosphate that might have been added by human activity such as a burial), it was found that the total phosphate content of the two soil layers was not markedly different, but the organic phosphate content had markedly decreased. In the present-day soil samples the organic phosphate was about 30–40% of the total, a value which is characteristic of many soils[7], while in the buried soil the organic phosphate fraction was only 10–15%. As far as can be determined from these three observations, the extent to which organic phosphate had been lost does not seem to depend on the length of time that the soil had been buried. Possibly partial hydrolysis took place quite quickly[5], but the occlusion was in each case a single event, and it is not possible to say anything about the kinetics.

The collection of a large number of soil samples from a 2 × 2 m sondage excavated in a Yugoslav tell site has enabled phosphate analyses to be made on soils which have been buried for various times, thus making it possible in principle to plot the progress of mineralization against time. The site, tell Gomolava on the Sava River about 80 km west of Belgrade, lies in a district of

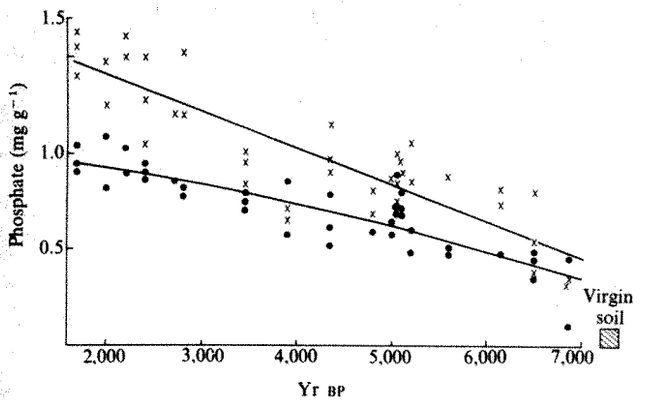

Fig. 1 Total phosphate (× and upper line) and inorganic phosphate (● and lower line) in soil samples from tell Gomolava, Yugoslavia. The lines show the best fit to the points predicted by an optimization routine. The basis of the model used for fitting is described in the text.

calcareous loess (*p*H 8–8.5), so that it is possible completely to exclude leaching. Unlike the three sites mentioned above, the total phosphate content of the buried virgin soil is very low, about 0.15 mg g^{-1}, so that almost all the phosphate in the archaeological samples must have come directly or indirectly from human activity. This has introduced complications in the interpretation of the results, but there are several points of interest that do not appear in a straight comparison of natural soils. The sondage was taken down about 6 m to virgin soil; the layer immediately above this is estimated to have been deposited in the early Vinča–Pločnik period (about 6,850 yr BP). The tell was occupied more or less continuously until sub-Roman times, so that the samples span a range of rather more than 5,000 calendar years (1,600–6,850 yr BP). The dating of the layers, by radiocarbon dating and by traditional archaeological methods (for example, by ceramic typology and by coin dating in the La Tène and Roman eras) is discussed in detail elsewhere[8]. It can be regarded as fairly reliable.

The analytical methods have been described earlier[1]. Total phosphate was measured by a nitrate incineration procedure, and inorganic phosphate by a 15-min extraction with 2 M HCl at 100 °C. About 130 soil samples were assayed for total phosphate. Approximately 50, selected to cover all the 19 archaeological strata, each about 30 cm deep, were chosen at random within the replicate samples available for each layer and assayed for inorganic phosphate. Organic phosphate was taken as the difference between the two measurements on a single soil sample.

The overall results for total and inorganic phosphate, for the soil samples that were subjected to both analyses, are shown in Fig. 1. Because the occupation density was markedly greater in Iron Age and Roman times than in the Neolithic, the total phosphate content of the excavated soil decreases with age, although even in the earliest Vinča–Pločnik layers it is clearly greater than that of the buried virgin soil, as indicated by the block in the lower right-hand corner of Fig. 1. (No measurements for present-day 'virgin' soil are available because the entire surrounding district is now heavily cultivated.) This variation makes it difficult to interpret changes in the relative inorganic phosphate content of soil samples of different ages. A simple mathematical model, with a straight line fitted to the total phosphate points, and assuming that the fraction of organic phosphate would be the same no matter when the soil was deposited, but that the organic fraction would be mineralized at a rate proportional to its concentration in the soil, produced the lower curve in Fig. 1. This fits the data reasonably well, but it gives a half-life for the organic phosphate of ~7,000 yr, with a decay constant that cannot be statistically distinguished from zero. This implies an infinite life for the organic phosphate fraction. Sections of the complete data were therefore examined in more detail (Figs 2, 3).

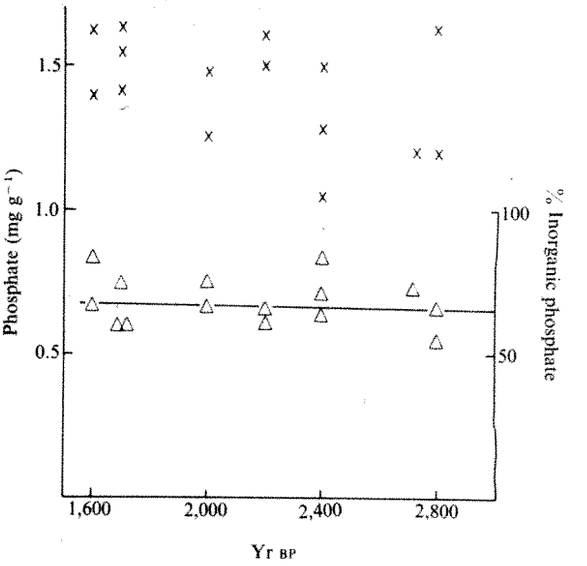

Fig. 2 Total phosphate (×) and inorganic phosphate as per cent of the total (△) over the period 1,600–2,800 yr BP at tell Gomolava. The line is the regresssion of the percentage points with time. It is not significantly different from zero, and the intercept lies at 66% (=34% organic phosphate).

Figure 2 shows the results for the period 1,600–2,800 yr BP, during which time the total phosphate content of the samples was reasonably constant, averaging 1.3 mg P per g dry soil. It can be seen that over this 1,200-yr period there is no evidence for mineralization. The inorganic phosphate content if anything decreased slightly with increasing age of sample. The same picture emerges from Fig. 3, which covers the period from 3,450 to 5,200 yr BP. (Allocation of the data to Figs 2 and 3 was dictated primarily by the lower total phosphate content of the samples shown in Fig. 3, averaging 0.9 mg P per g, but it corresponds also to a change in the nature of the settlements on the site, and of the palaeobotanical evidence, which is discussed in detail below.)

Consideration of Figs 2 and 3 suggests that over a total period of almost 4,000 yr, there is no evidence for conversion of the remanent organic phosphate into inorganic phosphate. It is however remarkable that the average organic phosphate content of the soils dated between 1,600 and 2,800 yr (Fig. 2) is about 34%, while that of the older samples (Fig. 3) is only about 12%. The difference is very consistent, and suggests that the two sets of soil samples had somewhat different histories, almost certainly before they were buried. Possible reasons for the difference are now discussed.

The transition point corresponds to the archaeological transition between Eneolithic and Copper Age cultures on the site (for example Baden and Kostalač) to full Bronze Age cultures (Vučedol, followed later by the Iron Age, Hallstatt and later cultures). It also corresponds almost exactly with a massive increase in the number of cereal seeds (mostly millet, einkorn and barley[9]) obtained from the sondage layers by flotation. It seems likely from the two pieces of evidence that there was a change from a subsistence still partly supplemented by hunting and fishing to one overwhelmingly based on cereal agriculture. A high proportion of the seeds found in the upper layers were charred, and thus brittle, so that one may realistically assume that the deposited soil will, from 3,000 yr BP onwards, contain a greater proportion of abraded grain than in earlier levels, whether the abrasion was caused by treading underfoot or by grinding into flour. The major organic phosphate compounds present in seeds, especially cereal seeds, are *myo*-inositol polyphosphates, principally phytic acid[7]. It is generally agreed that this class of compound is very stable in natural soil; it is thus reasonable to suppose that an important component of the organic phosphate fraction of the soil samples from the period

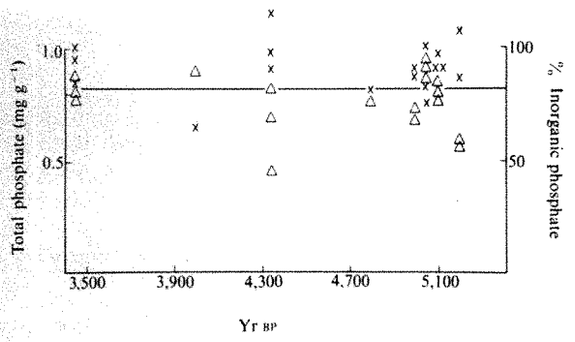

Fig. 3 Total phosphate (×) and inorganic phosphate as per cent of the total (△) over the period 3,400–5,600 yr BP at tell Gomolava. The line has the same significance as in Fig. 2, and the intercept lies at 88% (equivalent to 12% organic phosphate).

1,600–2,800 BP at tell Gomolava is comprised of inositol polyphosphates. As Fig. 2 provides no evidence of mineralization, it may be presumed that inositol polyphosphates are indeed completely resistant to biological attack in the conditions in which they were preserved. They would have been buried rather quickly, by collapse of mudbrick walls and the like[11], under as much as 30 cm of soil, on which a new phase of the settlement was then established. If confirmation can be obtained by direct analysis phytate would become an important addition to the list of resistant organic compounds whose identification can be of assistance to archaeologists and palaeoecologists.

In discussing the possible reasons for the lower proportion of organic phosphate found in the earlier buried soils, the results shown in Fig. 3, conclusions must be more tentative, because the argument has to be by analogy. There is no way of establishing what was the organic phosphate content of those soils when they were buried. One can only say that it must have been much higher in absolute amount than that of the buried virgin soil, because the organic phosphate content of the former is even now as great as the total phosphate of the latter. If the original organic phosphate of the soils buried earlier than ~3,000 yr BP did not come predominantly from cereal grains, it must nevertheless in some way have been synthesized. Almost certainly much of it was synthesized from the phosphate, largely inorganic, added to the soil by human and animal excretion. Except in the very earliest habitation levels on the site, the total phosphate of the soil was sixfold greater than that of the virgin soil. The soil phosphate cycle is sufficiently well understood[10] for it to be extremely probable that the organic components were synthesized as the result of a symbiosis between plant growth and soil microbial activity. If this reasoning is correct, the original organic phosphate may well have been considerably higher than 12% of the total, with fairly rapid mineralization of much of it. Gardiner and Walsh[5] concluded that this had been the case, both in the soil that they studied, and in the English buried soil[4].

This interpretation of events is of interest because it implies that until the middle of the fourth millennium the site was covered, at least in part, by vegetation. This idea is attractive for the following reasons. The density of settlement was much less in Neolithic times than later, and it seems unlikely that the whole tell surface, originally some 2–3 hectares in extent, was continuously occupied. It has been suggested that parts of the tell were in Neolithic times covered by local vegetation for quite long periods[9]. It is even possible that some cereal culture was carried out on the tell itself, as it was originally surrounded by extensive marshes bordering the Sava. The composition of the buried virgin soil, and of the clay exposed on the river bank, suggests that phosphate may have been rate-limiting for growth, so that vegetation would have grown rapidly when the tell surface received deposits of phosphate and also of nitrogen, from the settlers and their domestic animals.

This analysis of the results therefore suggests two phases in the development of the tell. In an earlier phase the tell resembled an island slightly raised above the surrounding marsh, and patchily settled by people who raised the fertility of the soil but did not prevent it from metabolizing phosphates in a way characteristic of normal soils. This was followed by a later phase in which settlement was much more intense, so that vegetation was necessarily much sparser. In addition, it seems possible that in the later phase, pre-formed organic phosphates (probably phytate) may have been deposited on the transient surface by changes in dietary and agricultural habits, but were not incorporated into the soil structure. This analysis agrees closely with what has already been deduced about the history of the tell from geological and palaeoecological observations[9,12]. The transition between the occurrence of shade-loving and open-country snails at the end of the Neolithic[9] is particularly significant in this regard.

It may be felt that this interpretation of the analytical results depends very heavily on inference and analogy. It is, however, susceptible to test in the following way. Although the reasons are not understood, it is known that the inositol in phytic acid is entirely the *myo*-isomer[7], while that in the inositol polyphosphates extracted from a variety of natural soils contains a mixture of the *myo*-, *chiro*-, *scyllo*- and *neo*-isomers of inositol[10,13]. Thus extraction of the inositol polyphosphates from earlier and later soil samples from tell Gomolava, followed by identification of the isomers, should make it possible to demonstrate whether the inositol in the later soils came predominantly from cereal grains, while that in the earlier soils has the isomeric composition characteristic of a stable natural soil, even though it is now part of an artificial mound. A programme of research to this end has been initiated in this laboratory.

The cytochrome P450-containing mixed function oxidases metabolize a variety of endogenous and exogenous compounds including drugs, carcinogens, fatty acids and steroids[1]. Mixed function oxidases have been detected in several tissues[2], including brain[3]. The enzyme system consists of a lipid fraction (phosphatidylcholine), cytochrome P450 and NADPH-cytochrome P450 reductase[4]. NADPH-cytochrome P450 reductase has been purified to apparent homogeneity and demonstrated to supply reducing equivalents from NADPH to cytochrome P450 (refs 5–7). Detection of NADPH-cytochrome P450 reductase thus represents an indirect means of demonstrating the presence

© 1984 Macmillan Journals Ltd

of cytochrome P450. Although the role of cytochrome P450 in the central nervous system (CNS) is not known, it may include such different functions as metabolism of xenobiotics[8], aromatization of androgens to oestrogens[9] and the formation of catecholoestrogens[10]. Despite the potentially very important role(s) of cytochrome P450 in brain function, its exact regional distribution remains essentially unknown. Using a specific antibody against rat liver NADPH-cytochrome P450 reductase in combination with immunohistochemical techniques, we have now localized this enzyme to defined catecholamine (CA)-containing structures of the rat and monkey brain.

NADPH-cytochrome P450 reductase purified from rat liver microsomes according to the method of Guengerich and Martin[11] with minor modifications[12], was >95% pure as judged by SDS-polyacrylamide gel electrophoresis[13]. Protein concentrations were determined by the method of Lowry *et al.*[14]. Antibodies to the enzyme were raised in rabbits and IgG fractions were isolated from the serum by affinity chromatography using a protein A–Sepharose CL-4B column[15], then concentrated to contain 25 mg protein ml^{-1}. IgG was isolated in a similar way from preimmune serum. The IgG fractions were dialysed against phosphate-buffered saline (PBS; 10 mM potassium phosphate buffer *p*H 7.4, containing 0.15 M NaCl). The antibodies were specific for the antigen as judged by the following criteria[12]: inhibition of NADPH-cytochrome *c* reductase activity of the purified antigen and in rat liver microsomes; Ouchterlony immunodiffusion; and immunoblotting[16] (described in Fig. 3 legend).

For the immunohistochemical studies, 15 rats (Sprague–Dawley, 180 g; Anticimex, Stockholm) of both sexes and two female monkeys (Talapoin, 1 kg) were perfused with 4% (w/v) paraformaldehyde in 0.1 M phosphate buffer (*p*H 7.4), their brains removed and cut in a cryostat (at 10 μm thickness) or on a Vibratome (at 70 μm). The sections were incubated with anti-NADPH-cytochrome P450 reductase antibody (diluted 1:300 to 1:1,000 in PBS containing 0.3% Triton X-100) for 1–6 days and the antibody–antigen complex visualized using either the immunofluorescence method of Coons[17] or the avidin–biotin complex method of Hsu *et al.*[18]. In a separate study of the possible coexistence of NADPH-cytochrome P450 reductase and tyrosine hydroxylase (TH) within the same neurone, sections were incubated with either antibody and reacted with 4-chloronaphthol according to the methods of Nakane[19], Gu *et al.*[20] and Tramu *et al.*[21] (Fig. 2).

Neurones containing a strong NADPH-cytochrome P450 reductase-like immunoreactivity are present within neuronal cell bodies of the following brain areas: the substantia nigra (SN), the ventral tegmental area of Tsai, the rostral part of dorsal raphe, the nucleus locus coeruleus and the ventrolateral medulla region of both rats and monkeys. NADPH-cytochrome P450 reductase-positive neurones are present also in the periventricular nucleus of the hypothalamus, the nucleus arcuatus (including the tanycytes of this nucleus) and the medial aspect of the zona incerta (Fig. 1).

All the brain areas listed above are known to harbour neurones containing the catecholamines dopamine (DA), noradrenaline (NA) or adrenaline (A)[22].

As the catecholamines are dependent on TH for their synthesis[23], alternating sections were incubated with a well characterized anti-TH antibody[24,25]. Analysis of serial sections revealed an overlapping distribution of cell bodies containing TH- and NADPH-cytochrome P450 reductase-like immunoreactivity in the mes- and diencephalon and nerve terminals in the following forebrain regions: the striatum, nucleus accum-

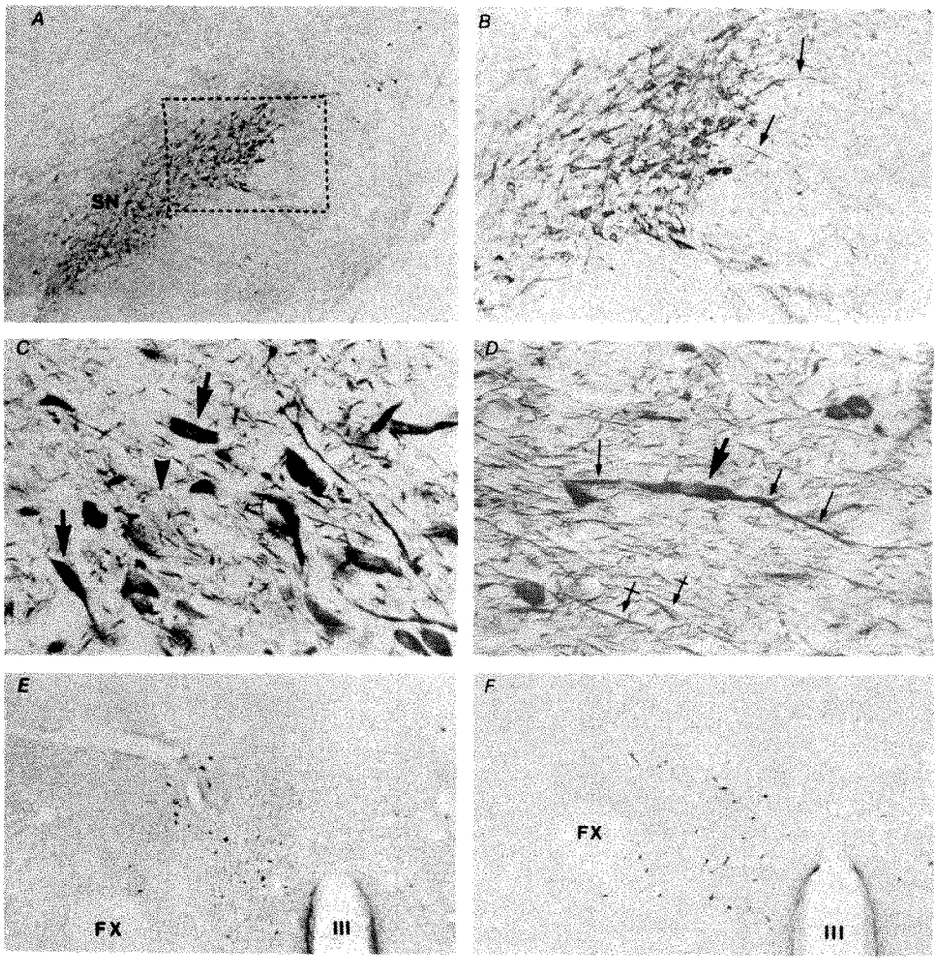

Fig. 1 *A–F*, Photomicrographs showing neurones in the substantia nigra (*A–D*) and hypothalamus (*E, F*) containing strong NADPH-cytochrome P450 reductase-like immunoreactivity. A large number of NADPH-cytochrome P450 reductase-positive cell bodies are present throughout the SN of the rat (*A*). The photomicrograph in *B* is an enlarged view of the enclosed area in *A*; arrows mark dendrites containing immunoreactivity. *C* And *D* show NADPH-cytochrome P450 reductase-positive neurones in pars compacta (arrows in *C*) and reticulata (large arrow in *D*) of the monkey SN. Small arrows in *D* indicate dendrites, and crossed arrows indicate dendrites of pars compacta cells that extend into reticulata. The substantia nigra of both rats and monkeys contains numerous cells lacking NADPH-cytochrome P450 reductase-like immunoreactivity (arrowhead in *C*). Incubations of sections in preimmune IgG or anti-NADPH-cytochrome P450 reductase IgG preabsorbed with the pure antigen (100 μg per 1,000 μl diluted antibody at 4 °C for 24 h) resulted in no staining in any of the brain regions examined. *E* And *F* show NADPH-cytochrome P450 reductase-positive neurones in the hypothalamus after incubation with the antibody alone (*E*) or antibody preabsorbed with pure TH (150 μg per 1,000 μl diluted antibody at 4 °C for 24 h (*F*). Note that preabsorption with TH did not block the staining of neurones with NADPH-cytochrome P450 reductase antibody. The peroxidase–anti-peroxidase method was used. Fig. 2 (*A–D*), Photomicrographs of neurones in the ventral tegmental area of Tsai (*A*, *B*) and the pars reticulata of the substantia nigra (*C*, *D*) in rat, demonstrating the simultaneous localization of TH (*A*, *C*) and NADPH-cytochrome P450 reductase-like immunoreactivity (*B*, *D*) within the same neurones.

Methods: Vibratome sections (70 μm) were incubated for 7 days in anti-TH antibody (diluted 1:2,000) and the antibody–antigen complex visualized using the avidin-biotin complex method with 4-chloronaphthol as a chromogen. The stained sections were coverslipped in PBS and glycerol (1:3) and the areas containing TH-like immunoreactivity photographed. The sections were subsequently decolourized in alcohol, eluted according to the method of Tramu *et al.*[21] and re-incubated in NADPH-cytochrome P450 reductase IgG (diluted 1:2000) for 5 days. The sections were reacted with 3′, 3′-diaminobenzidine and H_2O_2 to produce a brown reaction product. The stained sections were defatted, coverslipped in Pertex, re-photographed and analysed for the presence of double-labelled cells. Large arrowheads indicate cells containing both antigens. Small arrows in *B* mark cells containing NADPH-cytochrome P450 reductase but lacking TH-like immunoreactivity. Nomarski optics. ×500.

bens, olfactory tubercle and the septum. Lesions of the DA-containing axons ascending from the SN to the striatum in the lateral hypothalamus by infusions of the catecholamine neurotoxin 6-hydroxydopamine (6-OHDA, 8 μg per 4 μl; survival time of 10 days) resulted in a loss of NADPH-cytochrome P450 reductase and TH-like immunoreactivity from the striatum, accompanied by an increased intensity of immunoreactivity in the cell bodies of the SN ipsilateral to the lesion. These experiments suggest a coexistence of NADPH-cytochrome P450 reductase and TH in dopaminergic neurones of the SN. In separate experiments where the anti-NADPH-cytochrome P450 reductase antibody was preabsorbed with pure TH before incubation of the sections, staining of neurones in the SN and hypothalamus occurred to the same extent as after incubations with non-absorbed antiserum. Taken together, these findings show that the anti-NADPH-cytochrome P450 reductase antibody does not cross-react with TH and suggest that NADPH-cytochrome P450 reductase and TH occur in the same population of neurones. This hypothesis was confirmed by direct double

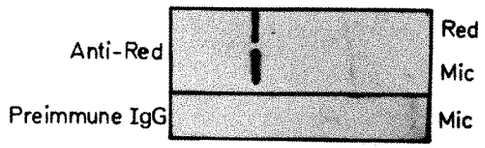

Fig. 3 Autoradiogram of an immunoblot showing the presence of NADPH-cytochrome P450 reductase (Red) in a microsomal fraction isolated from rat brain. Microsomes were isolated from the substantia nigra, ventral tegmental area of Tsai, striatum, nucleus accumbens and olfactory tubercle. Microsomes were prepared according to the procedure described by Holtzman and Desautel[31]. Immunoblotting was performed by the method of Towbin *et al.*[16] with minor modifications[12]. SDS-polyacrylamide gel electrophoresis[13] was performed using 8% acrylamide and 2.7 mm-thick slab gels. Proteins were transferred to nitrocellulose sheets which were then incubated for 2 h with antibody (or preimmune IgG) against rat liver NADPH-cytochrome P450 reductase (IgG fraction). The immunoreactive bands were visualized on the nitrocellulose filters using ^{125}I-labelled protein A followed by autoradiography. In the above experiment 0.1 μg of purified NADPH-cytochrome P450 reductase and 42 μg of brain microsomal protein (Mic) were run on the gel. The top part of the nitrocellulose filter was incubated with anti-NADPH-cytochrome P450 reductase IgG whereas the lower part was incubated with preimmune IgG. NADPH-cytochrome P450 reductase having a molecular weight similar to purified rat liver NADPH-cytochrome P450 reductase was detected in brain microsomes.

labelling experiments in which the same neurone in the SN (and hypothalamus) was found to contain both NADPH-cytochrome P450 reductase and TH-like immunoreactivity. A closer inspection revealed that while most, if not all, TH-positive cells contained NADPH-cytochrome P450 reductase, many reductase-positive neurones contained no TH immunoreactivity (Fig. 2).

The present study represents the first histochemical demonstration of NADPH-cytochrome P450 reductase in brain. The presence of NADPH-cytochrome P450 reductase-like immunoreactivity in central neurones supports earlier biochemical findings of this enzyme in brain[26]. Our study further extends the biochemical findings by identifying those neurones in the rat and monkey brain that contain the NADPH-cytochrome P450 reductase and thus possibly also cytochrome P450. It seems unlikely that the presence of NADPH-cytochrome P450 reductase and TH-like immunoreactivity in the same cell is due to cross-reactivity of the antibodies as preabsorption of anti-NADPH-cytochrome P450 reductase IgG with excess pure TH (and, conversely, anti-TH antiserum with excess pure NADPH-cytochrome P450 reductase) failed to block the subsequent immunostaining of central neurones.

Figure 3 shows that a protein having the same apparent molecular weight as the purified rat liver NADPH-cytochrome P450 reductase was found in brain microsomes. The part of the immunoblot which was incubated with preimmune IgG showed no reaction. This experiment supports the immunohistochemical data indicating the presence of NADPH-cytochrome P450 in the above-mentioned areas of the brain.

The presence of NADPH-cytochrome P450 reductase immunoreactivity in TH-positive cells probably indicates the existence of a cytochrome P450 system within these neurones. This is of particular interest as cytochrome P450 has been implicated in the formation of catecholoestrogens. The conversion of oestradiol and oestrone to catecholoestrogens has been demonstrated in the CNS of rat[27] and it is probable that the enzyme responsible for this conversion in the brain is similar to the cytochrome P450 found in peripheral tissue[10]. The action of the catecholoestrogens in the CNS has been linked to their interaction with biogenic amines as competitive inhibitors of catechol-*O*-methyltransferase (COMT)[28] and as possible inhibitors of TH[29] although it could also imply that catecholamines are being synthesized through an alternative pathway involving cytochrome P450.

Although the presence of NADPH-cytochrome P450 reductase in central catecholaminergic neurones strongly indicates

the existence of cytochrome P450 within these neurones, it cannot be excluded that this enzyme may have functions not directly linked to cytochrome P450. This could involve the donation of electrons from NADPH to cytochrome b_5—another electron transfer component identified in brain microsomes[30]. It has also been proposed[26] that NADPH-cytochrome P450 reductase could be involved in the formation of the catecholamine neurotoxin 6-OHDA. It may be speculated that the presence of large amounts of NADPH-cytochrome P450 reductase in central dopaminergic neurones may be of relevance for the formation of endogenous 6-OHDA in the development of neurodegenerative disorders such as Parkinson's disease.

We thank Dr James Halpert for providing the purified NADPH-cytochrome P450 reductase. This study was supported by grants from the Swedish MRC (13X-2819).

Effect of impulse blockage on cytochrome oxidase activity in monkey visual system

M. Wong-Riley & E. W. Carroll

Department of Anatomy, Medical College of Wisconsin, Milwaukee, Wisconsin 53226, USA

Cytochrome oxidase (cytochrome *c* oxidase; ferrocytochrome *c*: oxygen oxidoreductase, EC 1.9.2.1) has been introduced as an oxidative metabolic marker for neurones in the central nervous system[1]. Previous studies have shown that mature neurones remained sensitive to altered functional demands[2–9], and that both developing and adult neurones responded to sensory deprivation or deafferentation by reducing their cytochrome oxidase (Cyt.Ox.) activity[1,3,4,9–11]. More recently, we showed that the blockage of retinal impulse transmission with tetrodotoxin led to a reversible reduction in Cyt.Ox. staining of affected lateral geniculate (LGN) and striate neurones in adult cats[9]. The present study sought to extend these findings to adult monkeys, where Cyt.Ox. 'puffs' or 'blobs' are uniquely present in the visual cortex[10,12–14]. We found that, while the retina remained histologically intact, with only moderate decreases in Cyt.Ox. staining of large ganglion cells and the two plexiform layers, subtle changes occurred in the LGN as early as 1 day post-tetrodotoxin injection, and clear reduction in enzyme levels was evident in both the LGN and the visual cortex by 3 days. Changes became progressively more severe up to 4 weeks post-injection. Within area 17, alternating bands of high and low Cyt.Ox. staining occurred in lamina IV, with alternating rows of dark and lightly reactive puffs superimposed in exact register. Thus, the mature visual neurones in the primate remain extremely sensitive to the cessation of retinal impulse transmission, and plastic metabolic changes occur through several synapses along the sensory pathway.

Seven adult monkeys (*Macaca mulatta*) were used; six were experimental and one, plus a normal *Macaca fascicularis*, served as controls. The experimental monkeys were all anaesthetized with ketamine-HCl (15–30 mg per kg intramuscularly), and each received a unilateral intravitreal injection of tetrodotoxin (TTX, 19 μg in 10 μl of sterile water, a dosage found not to block axoplasmic transport)[9]. The pupillary light reflex was again used as a convenient indicator of the impulse blockage effect of TTX which, in the macaque, lasted for at least 4 days per injection. Injections were repeated twice weekly where applicable, and survivals were 1, 3, 6, 14 and 28 days. The animals were then perfused and all eyes and brains were frozen sectioned and processed for Cyt.Ox. histochemistry[1].

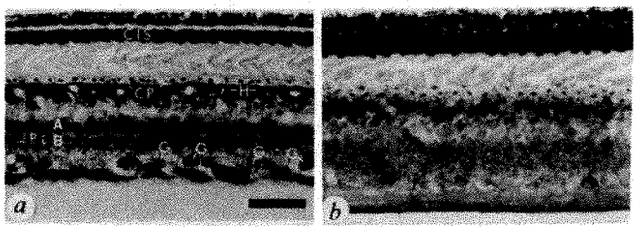

Fig. 1 Transverse sections through the normal (*a*) and TTX-injected (for 2 weeks) (*b*) retinae of a macaque. Sections have been reacted for cytochrome oxidase without counterstaining. In the normal retina, note the dense staining of cone inner segments (CIS), cone pedicles (CP), horizontal cells (H) and scattered large ganglion cells (G, arrows). The moderately stained inner plexiform layer (IPL) is subdivided into A and B, with B being slightly more reactive than A and exhibiting two thin bands of reactivity. The TTX-treated retina shows slightly decreased staining of the outer and inner plexiform layers and of the large ganglion cells. Scale bar, 50 μm.

The normal retinae of monkeys (as well as those of cats, ferrets and other mammals[15,16]) exhibited a distinct pattern of Cyt.Ox staining (Fig. 1*a*). From the photoreceptor layer inward, we found a highly reactive band of cone inner segments, a row of reactive cone pedicles and a row of reactive horizontal cell bodies with some moderately reactive bipolar cells. The inner plexiform layer contained a moderately reactive sublamina A and a slightly more reactive sublamina B, which included two thin reactive bands separated by a relatively clear zone. Finally, the large ganglion cells tended to be the most reactive, and they were scattered amongst slightly less reactive medium and small ganglion cells. The ganglion cell axons were reactive until they formed the optic nerve bundle, at which point they acquired myelin and lost their intense Cyt.Ox. activity.

In the normal macaque LGN, the two magnocellular layers and lamina 6 showed the highest level of Cyt.Ox. activity for both neurones and neuropil, with lamina 5 being moderately reactive and laminae 3 and 4 the least reactive (Fig. 2*a*) (see also ref. 15). Due to the greater cellular density in lamina 1, it appeared slightly more reactive than lamina 2. The S layer and the interlaminar zones contained relatively non-reactive neuropil and small neurones with occasional moderately reactive medium-sized neurones. In addition, all of the major cellular layers along the medial and lateral boundaries of the LGN, representing more peripheral portions of the visual field[17],

0028-0836/84/030262—03$01.00

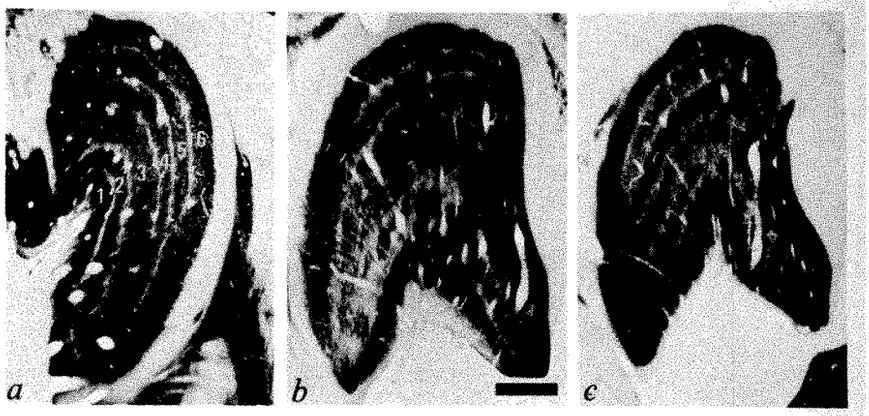

Fig. 2 Transverse sections through the macaque LGN reacted for Cyt.Ox. In the normal LGN (*a*), magnocellular laminae 1 and 2 and parvocellular lamina 6 are the most reactive. Lamina 5 is moderately reactive, while laminae 3 and 4 are the least reactive. After TTX injections, laminae 1, 4 and 6 that are contralateral, and 2, 3 and 5 that are ipsilateral to the injected eye exhibit decreased Cyt.Ox. activity. This pattern, shown here as ipsilateral to the injected eyes, can be seen by 3 days post-injection (*b*), but becomes more severe by week 4 (*c*). Scale bar, 1 mm.

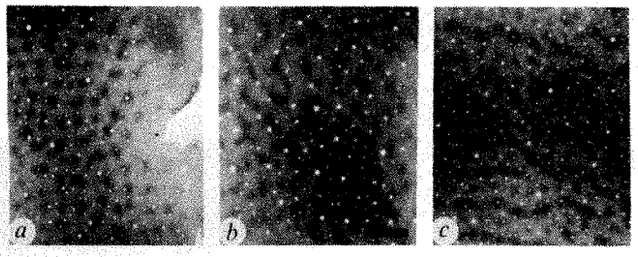

Fig. 3 Tangential sections through Cyt.Ox.-rich puffs in laminae II–III of macaque striate cortex reacted for Cyt.Ox. *a* Shows the normal distribution (see text). After 3 days of TTX treatment (*b*), a slight decrease in enzyme staining can be seen in some of the puffs which have been traced to be in register with lightly reactive bands in lamina IVC. After 4 weeks of TTX treatment (C), distinct rows of lightly reactive and shrunken puffs can be seen alternating with rows of darkly reactive puffs. These rows have been traced to line up in exact register with lightly reactive and darkly reactive bands respectively in lamina IVC (see Fig. 5). Scale bar, 1 mm.

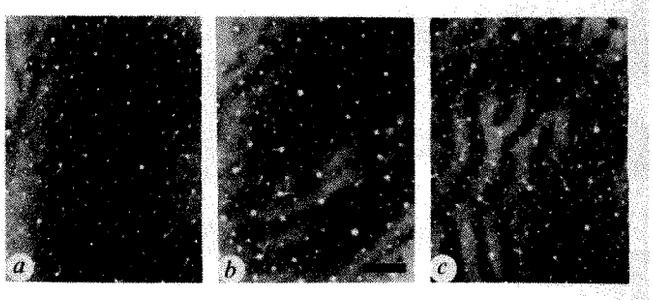

Fig. 4 Tangential sections through lamina IVC of macaque striate cortex reacted for Cyt.Ox. *a* Shows a homogeneous distribution of enzyme activity in the normal monkey. After 3 days of TTX injections (*b*), alternating bands of high and low Cyt.Ox. activity can be seen in IVC. This pattern becomes more distinct after 4 weeks of TTX injections (*c*). Scale bar, 1 mm.

exhibited a higher level of Cyt.Ox. activity than the middle portion of the nucleus.

The pattern of Cyt.Ox. staining in the normal striate cortex of the macaque was similar to that reported previously[10,18–20]. In the supragranular layers, the Cyt.Ox.-rich zones or puffs[13,14] were globular in shape, measuring ~262 μm × 377 μm (Fig. 3*a*). The puffs lined up in rows roughly orthogonal to the 17/18 border. The centre-to-centre spacing of puffs within the rows was 450 μm, while those between rows was about 353 μm. Lamina IV was also reactive (Fig. 4*a*), with lamina IVA having an intermittent punctate appearance, lamina IVCα being slightly more reactive than lamina IVCβ, and the lower edge of lamina IVCβ forming a thin band of darker staining. Laminae IVB and V were relatively non-reactive, while lamina VI was again moderately reactive. Reactive neurones, mainly of the stellate type, were seen in all of the cellular laminae. Reactive pyramidal cells were found mainly in laminae II–III, V and upper VI. These findings were comparable with our results in squirrel monkeys[13,14].

The effect of TTX on the retina was relatively mild. Even after 4 weeks of injections, the retina appeared remarkably intact histologically, and the pattern of staining remained essentially the same as normal. The major change was a decrease in the level of reactivity of large ganglion cells as well as those of the outer and inner plexiform layers (Fig. 1*b*).

As early as 1 day after TTX treatment, a mild decrease in the level of Cyt.Ox. staining was seen in laminae 2, 3 and 5 of the ipsilateral LGN, while laminae 1, 4 and 6 of the contralateral LGN appeared relatively normal. By 3 days changes were seen in all of the laminae innervated by the TTX-treated eye (Fig. 2*b*) and the severity increased with longer survivals. Because laminae 1 and 6 were normally quite reactive, they were the last ones to exhibit a level of Cyt.Ox. staining that was lower than that of non-TTX-treated laminae. After 4 weeks of TTX injections, distinct differences were seen between reactive and TTX-affected laminae (Fig. 2*c*). At all survival periods, the ipsilateral laminae suffered a greater reduction of Cyt.Ox. than the contralateral ones.

TTX treatment for 1 day did not reveal significant alterations in enzyme staining or overall dimensions of laminae II–III puffs in the striate cortex. Changes in lamina IV were subtle, with minor fluctuations in staining within lamina IVC. By 3 days, however, alternating bands of high and low Cyt.Ox activity were clearly visible within lamina IVC (Fig. 4*b*). The puffs exhibited some disarray, with slightly shrunken, paler puffs scattered amidst darkly reactive ones (Fig. 3*b*). Serial tracings of tangential sections (see Fig. 5 legend) confirmed that rows of reactive puffs stayed within the confines of reactive bands in lamina IVC, while rows of light puffs fell within those of light bands in lamina IVC. This pattern of alternating dark and light puffs/bands became more prominent with longer survivals up to 4 weeks (Figs 3*c*, 4*c*, 5). Moreover, light puffs appeared progressively smaller. In register with the pattern in the upper layers, laminae V and especially lamina VI showed alternating bands of dark and light Cyt.Ox reactivity. At each survival time, the overall dimensions of reactive puffs were comparable with those in control monkeys. However, even at 3 day survival, there was a significant difference ($P \ll 0.001$) in cross-sectional areas between reactive and non-reactive puffs (56,372.211 μm^2 compared with 39,870.51 μm^2). By 4 weeks, this difference was even more pronounced (55,504.347 μm^2 and 17,859.168 μm^2, $P \ll 0.001$). On the other hand, the centre-to-centre spacing between reactive puffs of the same row, between non-reactive puffs of the same row, and between puffs of adjacent rows remained essentially the same as the control.

The possibility that these transneuronal and trans-trans-neuronal enzymatic alterations might be due to retinal damage was deemed unlikely because: (1) All TTX-injected eyes

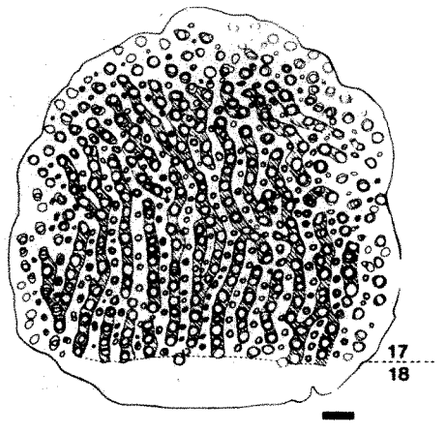

Fig. 5 Composite camera lucida tracings through nine serial tangential sections (spanning a depth of 550 μm) from area 17 of a macaque whose contralateral eye has been injected with TTX for 4 weeks. Note that the large, darkly reactive puffs lie in exact register with darkly reactive bands (hatched) in lamina IVC, while the shrunken, lightly reactive puffs are superimposed over lightly reactive bands in lamina IVC. Scale bar, 1 mm. Tracings such as this were done in the control as well as 11 of the experimental hemispheres. For each hemisphere, the areas of at least 100 puffs overlying the reactive bands, and 100 overlying the non-reactive bands in lamina IVC of each composite tracing were digitized with the aid of a computer. Statistical analyses were done for the mean areas of reactive and non-reactive puffs, and comparisons made between these two groups at different survival periods.

remained histologically intact, similar to the control; (2) the ganglion cells of the injected eyes retained their ability readily to transport tritium-labelled tracers to the LGN (our unpublished observations); (3) the observed response in the striate cortex was rapid (within 3 days and after only a single injection) and widespread rather than localized; and (4) our findings in the cat[9] and our preliminary results in the monkey indicated that these enzymatic adjustments were reversible. Moreover, histochemical changes appeared to be more dramatic in the brain itself than in the retina (see note added in proof).

The present study thus indicates that the mature primate visual system remains extremely sensitive to the cessation of retinal impulse transmission. Tetrodotoxin is known to cause altered functional properties in the developing kitten visual system[21,22], but the adult sensory system was thought to be refractory to the detrimental effect of sensory deprivation. Our present results demonstrate that, not only are changes pronounced at both the geniculate and cortical levels, but the swift onset of transneuronal and trans-transneuronal responses is much more dramatic than our earlier findings in the cat (1 week)[9], and of reported geniculate cell shrinkage and cortical enzyme changes after a more drastic procedure of enucleation (10 days)[11,23,24]. The primate visual neurones, then, respond briskly to the blockage of retinal input, even while the system remains structurally intact, and axoplasmic transport is retained. The metabolic changes do not occur uniformly throughout the LGN. Neurones which receive ipsilateral input appear to suffer the consequences slightly earlier and to a greater extent than those receiving contralateral input, as we have observed in the cat[9]. Likewise, neurones representing the central portion of the visual field seem to be more affected than the peripheral ones. Changes in cortical lamina IVC and the puffs indicate that their energy-coupled activities are very much controlled by retinal input. The dark and light bandings in lamina IVC correspond in spacing and dimensions to ocular dominance columns described by Hubel's group[25], and are the known sites for geniculocortical terminations[26–28]. The sources of input to the Cyt.Ox. puffs have been postulated to arise from the interlaminar and S layers of the LGN[29,30], although other inputs have not yet been ruled out. The histochemical 'shrinkage' of puffs suggests that, although the entire puff may suffer an overall lowered level of activity, there may be an additional tendency for the response to progress in a peripheral-to-central direction. In conclusion, we have demonstrated the dramatic and early response of mature primate neurones to the blockage of primary afferent impulses, indicating that the normal functional and enzymatic integrity of cortical neurones are very much governed by activity originating one to several synapses away.

Note added in proof: Our recent findings indicate that 2 weeks of unilateral intravitreal saline injections did not result in any histochemical changes in the visual system of the macaque.

Community food webs have scale-invariant structure

Frédéric Briand* & Joel E. Cohen†

* University of Ottawa, Department of Biology, Ontario, Canada K1N 6N5
† The Rockefeller University, 1230 York Avenue, New York, New York 10021, USA

We have analysed 62 community food webs drawn from published studies and have found a remarkable regularity in ecosystem structure: in biological communities, the proportions of top, intermediate and basal species are, on average, independent of the total number of species. Hence, there is a direct proportionality between the numbers of prey and predators.

The finding[1] that, in community food webs, the ratio of prey to predators is 3:4 may be challenged on two grounds: first, it is based on a relatively small set of 14 webs, and second it may indicate that taxonomists have exercised greater taxonomic refinement in classifying organisms at higher than at lower trophic levels[2].

A community food web involves the feeding, that is, trophic, relations among all organisms found in a well-defined habitat by the original investigator. Organisms are separated into 'trophic species', which may be a single biological species, or a size class or stage in the life cycle of a single biological species, or a collection of functionally or taxonomically related biological species, according to the original report. Throughout this paper a 'species' refers to a 'trophic species', not necessarily to a single

0028-0836/84/030264—04$01.00

biological species. A 'top' species is a predator that has no predator. An 'intermediate' species is a species that is both a predator and a prey. A 'basal' species is a prey that has no prey.

The community food webs analysed include 40 webs assembled and described by Briand[3]; of these, 13 are corrected and drawn from the 14 originally used by Cohen[1]. Details of the food webs not yet presented by Cohen[4] or Briand[3] will be published elsewhere (F.B., in preparation). We find that the number of prey is roughly proportional to the number of predators with a slope less than 1 (Fig. 1*a*). This is also true for webs from constant and fluctuating environments, although they are quite different in overall structure[3]. On the far right of Fig. 1*a*, four outliers emerge from the general relationship: a cluster of three constant food webs (C), all from Fryer's study[5] of littoral communities of Lake Nyasa, and one fluctuating food web (F) representing a salt meadow from New Zealand[6].

There can be no direct test of Pimm's conjecture[2] of why the slope is less than 1, without repeating the original field studies with a uniform attention to taxonomic detail. As an indirect test, we examined the ratio of prey to predators in the 62 food webs, after we had 'lumped' trophically identical species. That is, in each food web, whenever two or more species are preyed on by exactly the same set of predators, and prey upon exactly the same set of prey, we treated them as one. This procedure, which we call 'lumping', removes possible differences in the propensity to split, both among observers and among trophic levels.

Lumping moves the outliers into or much closer to the bulk of the remaining data points, for both fluctuating and constant webs (Fig. 1*b*). The correlation coefficient between numbers of predators and prey among the 43 fluctuating webs increases from 0.83 before lumping to 0.92 after, and from 0.58 to 0.64 among the 19 constant webs. In other words, eliminating predators or prey that are trophically identical tightens the relation between numbers of predators and prey.

Because individual observers tend to influence prey–predator ratios, we shall deal only with the lumped version of the webs. Because some observers contributed more than one food web to our collection, the assumption of independence that is required to justify attaching probability values to significance tests using the unlumped data is open to challenge. Though the assumption of independence is probably more acceptable with the lumped version of the webs, we shall base our statistical analysis primarily on descriptive statistics. Fortunately the patterns in the data are clear.

If a straight line, either with arbitrary intercept or through the origin, is fitted to a scatter plot of the 62 community food webs, the squared residuals increase with the number of predators. This reveals that the usual least-squares procedure, which assumes the variance of residuals constant regardless of the abscissa, is not appropriate to these data.

If a regression line is fitted through the origin on the assumption that the variance of the residuals is proportional to the number of predators, then the estimator of the slope is simply the ratio of the mean number of prey divided by the mean number of predators. Under this assumption, a straight line through the origin fitted to all 62 food webs has slope 0.8819 or approximately 0.9.

This slope is higher than the slope near 0.75 found by Cohen[1], so there appears to be some merit in Pimm's suggestion[2] that ecologists have exercised greater taxonomic refinement at high trophic levels than at low. This suggestion, however, is not quantitatively sufficient to account for the excess, that remains after lumping, in the number of predators over the number of prey.

Classical ecological theory views predators as generally limited by resources, and the diversity of predators in particular as being limited by the diversity of prey. From this perspective it would seem more natural to treat the number of prey as an independent variable and the number of predators as a dependent variable. However, when the number of predators is regressed against the number of prey, using a straight line through the origin with variance of residuals proportional to the abscissa, the standard error of estimate (with 61 degrees of freedom) increases from 3.1 to 3.5.

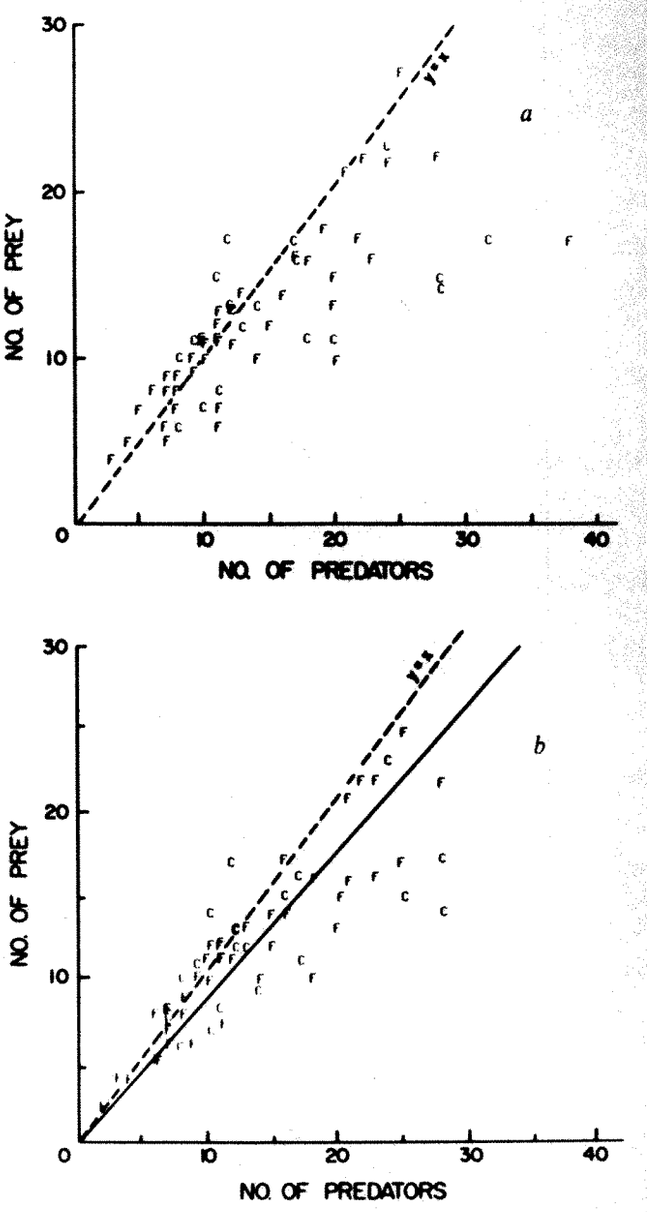

Fig. 1 Number of prey species as a function of number of predator species in 62 community food webs. F, fluctuating environment. C, constant environment. An environment is classified as 'fluctuating' if the original report indicates temporal variations of substantial magnitude in temperature, salinity, water availability, or any other major physical parameter. The magnitude, and not the predictability, of the fluctuations is the criterion of classification. The symbols F and C have been shifted from their exact locations by a small random amount to indicate when several food webs have exactly the same coordinates. *a*, Original data; *b*, after lumping. The solid line through the origin is fitted on the assumption that the variance of the residuals is proportional to the number of predators. The slope is 0.8819.

This observation means that the number of predators is a better predictor of the number of prey than the reverse. This raises the intriguing possibility that, in both constant and fluctuating environments, the number of predators is causally more important in controlling the number of prey than vice versa. Evidence and theory in favour of this suggestion have been independently reviewed by Jeffries and Lawton[7].

That we find a linear relationship between number of prey and number of predators is not too surprising, since the *x*- and

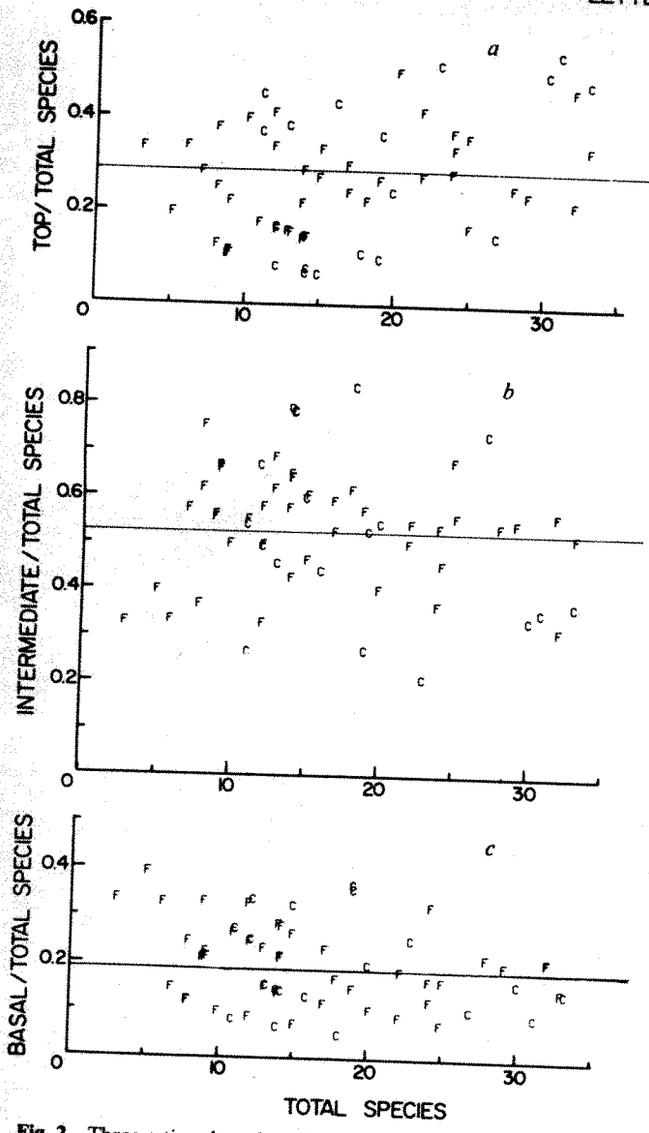

Fig. 2 Three ratios plotted as a function of the number of species. The fitted lines are constrained to be horizontal (slope = 0). *a*, Top species/total species. The height of the line is 0.2853. *b*, Intermediate species/total species. The height of the line is 0.5251. *c*, Basal species/total species. The height of the line is 0.1896.

y-axes share a similar quantity, namely the intermediate species, which are both prey and predators. What is surprising is the tightness of the fit, considering the size and heterogeneity of the sample examined. This suggests two possibilities: either the redundant variable, that is, the number of intermediate species, is very large compared with the number of basal and top species in most communities, or the proportions of all species in a food web that fall into each of these three categories are, overall, independent of the total number of species.

Figure 2 illustrates the reality of the second alternative: in the 62 webs examined, the fractions of top, intermediate and basal species are, on average, independent of the total number of species, although there is a slight tendency for the fraction of top species to increase and for the fraction of basal species to decrease as the total number of species increases. To obtain a global estimate of the proportions of species in each of the three categories (top, intermediate, basal), we summed over all food webs the observed numbers in each category, and divided by the sum total of species over all food webs. The global proportions of top, intermediate and basal species correspond to the heights of the horizontal lines in Fig. 2*a*–*c*.

The scatter of points about the horizontal lines in Fig. 2, when constant and fluctuating food webs are considered together, agrees with the hypothesis that in each food web the top, intermediate and basal species are multinomially sampled from the total species in proportions that are constant for all webs. If the species counts are arranged in a 3×62 contingency table with rows for top, intermediate and basal species and one column for each web, a homogeneity test yields a χ^2 of 138.9 with 122 d.f., which is not significant at the 0.1 level.

There is no evidence for a difference between constant and fluctuating food webs in the mean proportions of top, intermediate and basal species. A homogeneity test of a 3×2 contingency table with rows for top, intermediate and basal species and columns for constant and fluctuating food webs, and the summed species counts as cell entries, gives a χ^2 statistic of 1.4 with 2 d.f., which is not significant at the 0.1 level.

However, the proportions of top, intermediate and basal species in constant food webs, considered separately, are significantly more variable, and the proportions in fluctuating food webs, considered separately, are significantly less variable, than expected from multinomial sampling (using a 0.02 significance level). Separate homogeneity tests of the constant webs (in a 3×19 contingency table) and of the fluctuating webs (in a 3×43 contingency table) yield χ^2 of 82.8 with 36 d.f. and 56 with 84 d.f., respectively. The visual counterpart of this statistical result is the appearance in each panel of Fig. 2 of fluctuating food webs near the horizontal line and of constant food webs scattered above and below the band of fluctating webs. Food web structure appears more constrained in fluctuating than in constant environments, as previously noted[3,8].

We now show that the empirical regularities in Fig. 1*b* can be derived from the approximate scale-invariance shown in Fig. 2.

Let S be the total number of species in a single community food web, T the expected number of top species in that web, I the expected number of intermediate species, B the expected number of basal species, R the expected number of predators and Y the expected number of prey. By definition

$$S = T + I + B \tag{1}$$

$$R = T + I \tag{2}$$

$$Y = I + B \tag{3}$$

By observation

$$T/S = p \quad \text{or} \quad T = pS, \qquad \hat{p} = 0.2853 \text{ (Fig. 2}a\text{)} \tag{4}$$

$$I/S = q \quad \text{or} \quad I = qS, \qquad \hat{q} = 0.5251 \text{ (Fig. 2}b\text{)} \tag{5}$$

$$B/S = r \quad \text{or} \quad B = rS, \qquad \hat{r} = 0.1896 \text{ (Fig. 2}c\text{)} \tag{6}$$

Adding equations (5) and (6) and dividing by the sum of equations (4) and (5), we recover the observed regularity (Fig. 1*b*)

$$Y/R = a \quad \text{or} \quad Y = aR, \qquad a = (q+r)/(q+p) \tag{7}$$

The predicted value $(\hat{q}+\hat{r})/(\hat{q}+\hat{p}) = 0.8819$ is identical to the observed $\hat{a} = 0.8819$ because of the formulas we used to estimate the slope a and the proportions p, q and r. However, the observation in Fig. 1*b* that the average number of prey is a linear function of the number of predators is not a tautologous consequence of the estimation formulas. The proportionality of prey to predators follows from the scale-invariance we have discovered here. Were data available, it would be interesting to examine whether the distribution of biomass into top, intermediate and basal species is also scale-invariant.

We conclude that the values of any two of the three parameters p, q and r summarize succinctly a substantial amount of information about the empirical regularities found in community food webs and provide a factually grounded benchmark against which the deviations of particular food webs may be measured. Why these proportions take the values they do and why the proportions are scale-invariant remain open questions.

We thank Stuart Pimm, W. G. Sprules and P. Yodzis for their helpful comments. This work was supported by grants A9868 from the Natural Science and Engineering Research Council of Canada and DEB80-11026 from the USNSF.

Monoclonal antibody that identifies subsets of neurones in the central visual system of monkey and cat

S. H. C. Hendry*, S. Hockfield†, E. G. Jones* & R. McKay†

* James L. O'Leary Division of Experimental Neurology and Neurological Surgery and McDonnell Center for Studies of Higher Brain Function, Washington University School of Medicine, St Louis, Missouri 63110, USA
† Cold Spring Harbor Laboratory, Cold Spring Harbor, New York 11724, USA

Striking correlations between structure and function are found in the visual cortex of Old World primates[1–4]. These include the co-localization of glutamic acid decarboxylase (GAD, the biosynthetic enzyme of the inhibitory neurotransmitter, γ-aminobutyric acid) with the mitochondrial enzyme, cytochrome oxidase (CO)[5] in functionally distinct subcompartments[6,7] of ocular dominance columns[3,4,8]. We report here immunocytochemical studies with a monoclonal antibody (CAT 301)[9] showing that the antibody recognizes an uncharacterized antigen on surfaces of some neurones in certain layers of the monkey striate cortex (area 17), and in certain parts of the cat and monkey dorsal lateral geniculate nuclei (LGN). Patches of immunocytochemically stained neurones and neuropil, apparent in layers III, IVB and VI of the striate cortex of normal monkeys, become even more clearly delineated in animals from which one eye has been removed. The antibody-stained patches in the three layers line up radially with one another in lines passing through the centres of ocular dominance columns (demonstrable by CO staining in layers IVA and IVC). In layers III and VI the patches coexist with CO-positive patches[3,4] and, in the horizontal dimension, both antibody and CO-positive patches are aligned to form rows. Stained neurones in the monkey LGN are primarily in the magnocellular layers and in the cat LGN are confined to laminae A and A_1, the inter-laminar plexuses, the perigeniculate nucleus and the medial inter-laminar nucleus. The antigen we have localized is associated with particular cell populations, some of which may correspond to a specific, physiological class.

Three normal cynomolgus monkeys (*Macaca fascicularis*) and three cats were used. Three other monkeys were anaesthetized and one eye removed 8 or 10 days before they were re-anaesthetized and perfused with buffered 4% paraformaldehyde. Alternating frozen sections from both sides of the brains were processed immunocytochemically with CAT 301 (refs 9, 10) and histochemically for cytochrome oxidase[11].

CAT 301 stains pyramidal and nonpyramidal neurones particularly in layers IVB and VI of monkey striate cortex (Fig. 1); there is a diffuse staining of the neuropil around the stained cells (Fig. 1*a*). Some cells in layers II and III but very few in layers I, IVA, IVC or V are stained.

Within layers IVB and VI and deep in layer III, CAT 301-positive neurones form patches (Figs 2*a,c*, 3*a*). Patches in layers III and IVB are 200 μm × 150 μm; those in layer VI approach 300 μm. In tangential sections (Fig. 2) patches in layers IVB and VI form rows perpendicular to the border of areas 17 and 18. Gaps between patches vary in size from 300–500 μm along the rows to 200–400 μm between the rows (Fig. 2). Rows of patches are less distinct in layer III (Fig. 3).

In transverse sections most patches of CAT 301-positive cells in layer VI line up radially with patches in layers IVB and III (see Fig. 2). Less than 10% of those in layer VI are without overlying patches in layer IVB, but approximately 30% in layers VI and IVB have no corresponding patch in layer III.

Following the removal of one eye, the patchy distribution of CAT 301-positive cells in layer VI becomes much more distinct due to a sharp reduction in the neuropil staining at the edges of the patches.

Ocular dominance columns in area 17 are demonstrated by CO histochemistry after monocular enucleation (Fig. 2*b,d*). The columns are most obvious in layers IVA and IVC[2,12] but they can also be distinguished in layers III and VI.

By aligning radially oriented blood vessels, tangential sections in layer IVC reacted for CO can be superimposed on adjoining sections stained immunocytochemically with CAT 301. Patches of CAT 301-positive cells in layers III, IVB and VI are aligned with the centres of both CO-rich and CO-poor columns in layers IVA and IVC (Figs 2*a–c*), indicating that CAT 301-positive patches lie at the centres of both ipsilateral and contralateral ocular dominance columns. Where the stripes formed by ocular dominance columns branch, two side-by-side patches of CAT 301-positive cells appear in layers IVB and VI. Patches are also present where the monocular segment of the visual field is represented and ocular dominance columns are not demonstrable[2,12].

In layer III, 70% of the CO-positive periodicities of layer III of normal monkeys[3,4,7,8] (Fig. 3*a*) superimpose with CAT 301-positive patches (Fig. 3*b*). The remaining 30% are without corresponding CAT 301 patches. However, virtually all CO-positive periodicities in layer III line up radially with CAT 301 patches in layers IVB and VI.

In layer VI, with very few exceptions, patches of CAT 301-stained cells and patches of CO staining in layer VI are exactly superimposed (Fig. 2). Both lie at the centres of right- and left-eye dominance columns (Fig. 2*c,d*) and both are aligned in stripes.

In the LGN of enucleated and intact monkeys most cells (~95%) in the magnocellular layers and very few (<15%) in the parvocellular layers are CAT 301-positive (Fig. 4*a*). Stained cells vary from 18 to 24 μm in average diameter.

In the cat LGN, CAT 301-positive cells make up slightly more than 20% of the population of the A and A1 laminae and only 1 or 2% of the population of the C laminae. Stained cells average 20–25 μm in diameter. Most neurones in the inter-laminar zones, the perigeniculate nucleus and the ventral lateral geniculate nucleus, and approximately 80% of those in the medial interlaminar nucleus are labelled (Fig. 4*b*).

The striate cortex of Old World monkeys can be divided into a series of functional modules or 'hypercolumns'[1,2]. CO histochemistry has revealed a series of radially organized periodicities in layers II–III and V–VI[3,4] that occupy the centres of ocular dominance columns. Several reports, focused on the periodicities in layer III, document their structural[3,4,8] functional[6,7,10,13,14] and biochemical[5,15] properties and Livingstone and Hubel[4] have pointed out that they may be an indication that hypercolumns are structural entities with definite borders. We have demonstrated that neurones in monkey striate cortex stained with CAT 301, are also organized in radial arrays that align with the CO-rich periodicities. Like the CO-positive zones, CAT 301-positive patches occupy the centres of ocular dominance columns, further demonstrating that groups of neurones within the columns possess distinct properties.

CAT 301-positive patches in area 17 superficially resemble patches of cells described as giving rise to long intracortical axons[16] but, unlike CAT 301-positive patches, the long-axoned

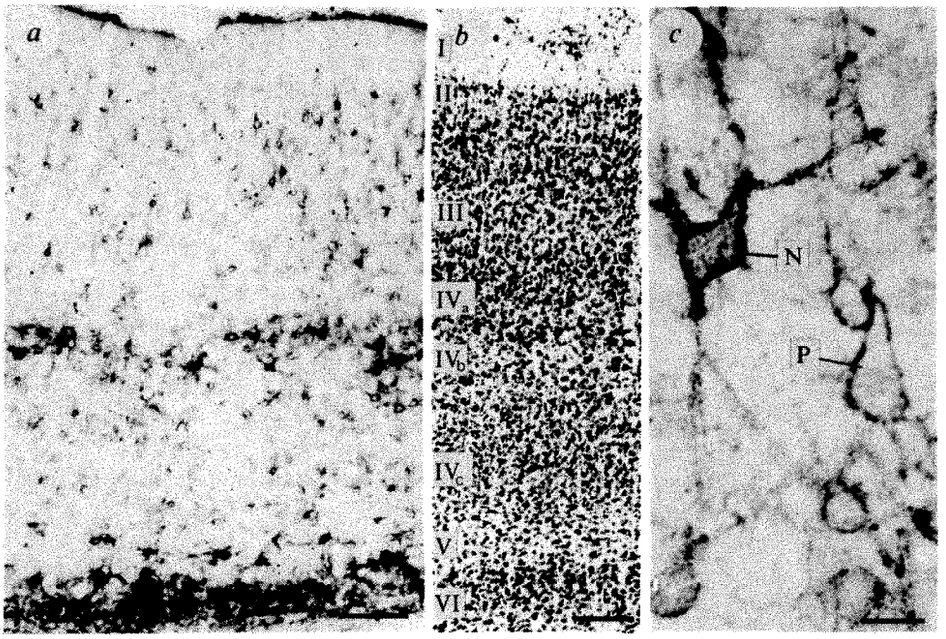

Fig. 1 *a*, Laminar distribution of CAT 301-positive neurones in a radial section through area 17 of a normal monkey. Dense bands of cells are stained in layers IVB and VI but very few cells are stained in other layers. *b*, Section adjacent to *a*, counterstained with thionin. Roman numerals indicate cortical laminae according to the scheme of Brodmann[26] as modified by Lund[27]. *c*, Higher magnification of CAT 301-positive cells in layer VI of same section as *a*. Both pyramidal (P) and non-pyramidal types are stained. Scale bars, 100 μm in *a* and *b*, 20 μm in *c*.

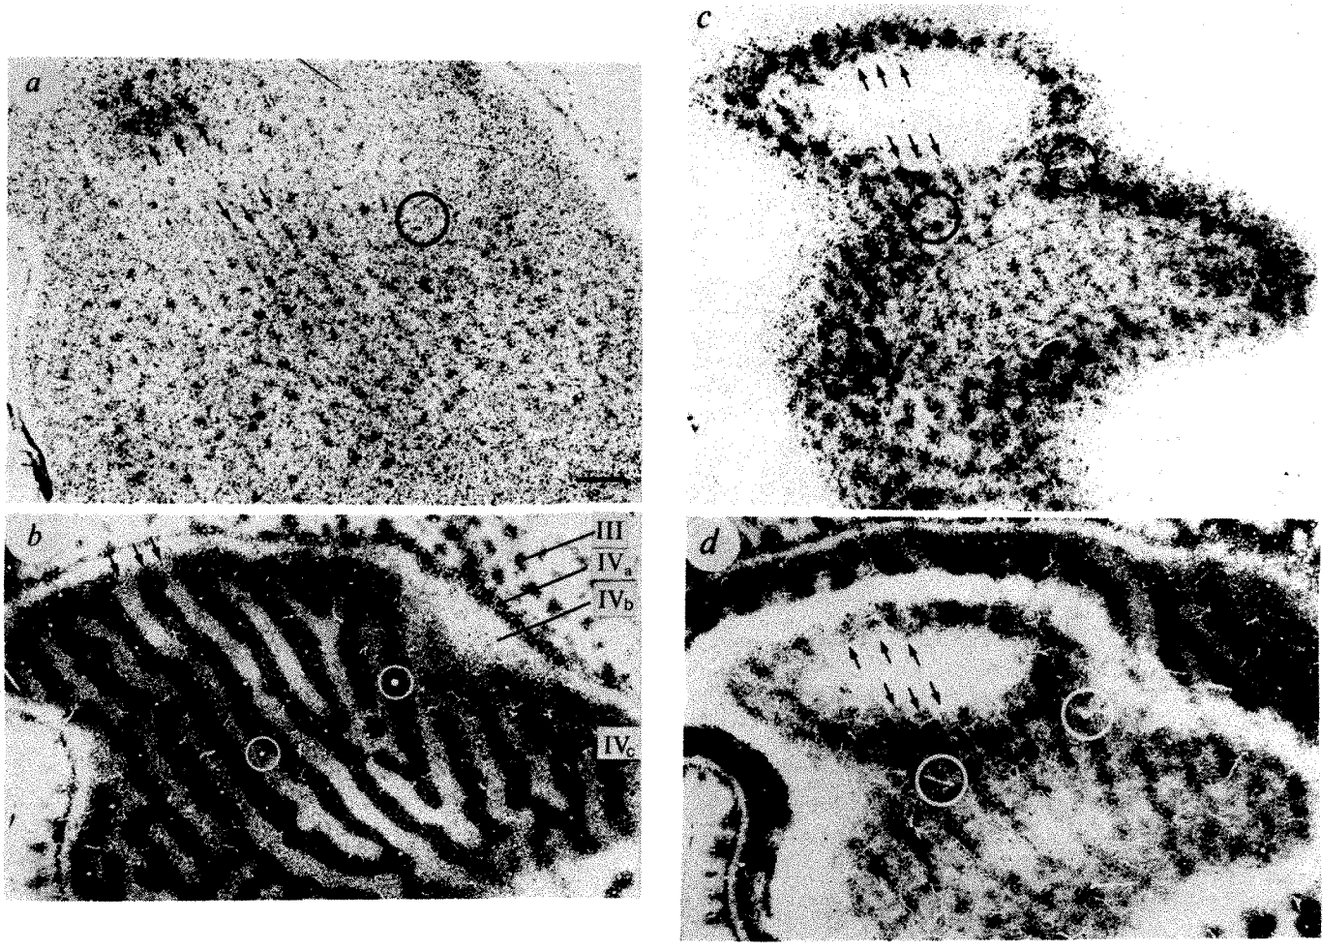

Fig. 2 Tangential sections (parallel to the brain surface) through area 17 of a monkey from which the contralateral eye was removed. *a*, Stained immunocytochemically by CAT 301, mainly through layer IVB; *b*, stained for CO, mainly through layer IVC. Alternating CO-rich and -poor bands represent ocular dominance stripes of intact and removed eyes, respectively. *c*, *d*, Stained by CAT 301 and for CO, respectively, mainly through layer VI. In *d* blanching of alternate rows of CO patches is an effect of the enucleation. Other layers indicated on *b* appear because plane of section is not perfectly parallel to the individual layers. The sections can be superimposed by aligning the penetrating blood vessels, two of which are circled. When this is done, the rows of CAT 301-stained periodicities can be seen to be in exact register with one another, with the ocular dominance stripes of layer IVC, and with the rows of CO-stained periodicities of layer VI. Three corresponding rows of patches and stripes are indicated by arrows. Note that the CO staining declines in ocular dominance stripes and patches related to the removed eye so that staining with CAT 301 is associated with both strongly and weakly CO-positive stripes and patches. Scale bar, 1 mm.

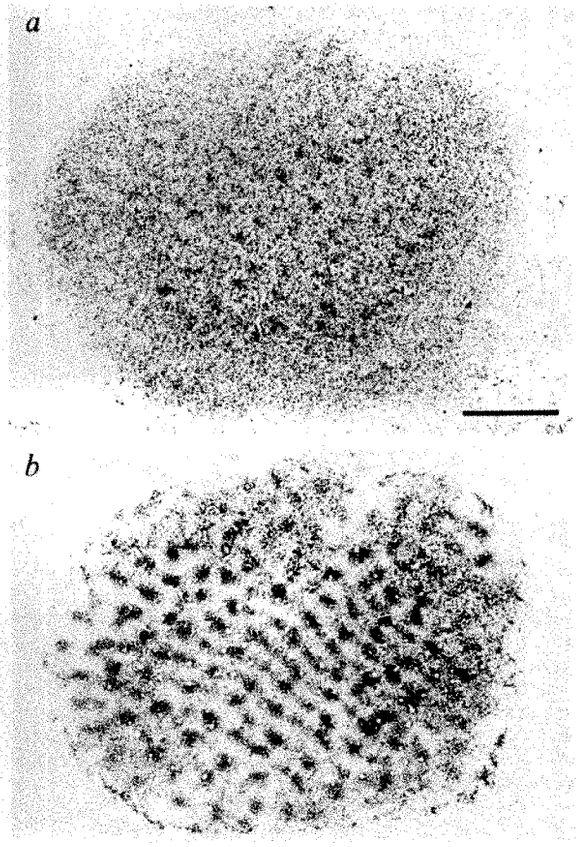

Fig. 3 Adjacent tangential sections through layer III in area 17 of a normal monkey. Patches of neurones stained immunocytochemically by CAT 301 (*a*) are aligned in rows that correspond to rows of cytochrome oxidase stained patches in the adjacent section (*b*). Many of the CAT 301-positive patches can be exactly superimposed on the CO positive densities. Scale bar, 2 mm.

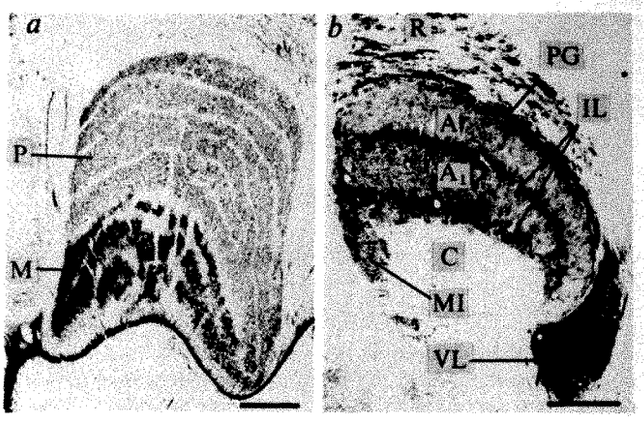

Fig. 4 Frontal sections of LGN from a monkey (*a*), and a cat (*b*), stained by CAT 301. *a*, In the monkey LGN there are many densely stained cells in the two magnocellular layers (M) and very few in the four parvocellular layers (P). The diffuse background staining of the parvocellular layers is not clearly associated with any neuronal processes. *b*, In the cat lateral geniculate complex, there is heavy staining of cells in the medial interlaminar nucleus (MI), the ventral lateral geniculate nucleus (VL), the perigeniculate nucleus (PG) and in the interlaminar plexuses (IL), with less staining of the A and A1 laminae and very little of the C laminae. Additional staining appears in the thalamic recticular nucleus (R). Scale bar, 1 mm.

cell patches are not correlated with CO-positive periodicities.

CO staining in layers III, IV and VI correlates with the termination of thalamic afferents[4]. CAT 301 patches coincide with CO staining in layers III and VI, but not in layers IVA or IVC where the heaviest thalamic terminations occur. CAT 301 is unlikely to mark afferent terminals directly because immunoelectron microscopy suggests that the surface antigen is extrasynaptic and synthesized by the cell which it outlines[10], that is, the postsynaptic cell is defined by the antigen.

The distribution of CAT 301-positive neurones in monkey visual cortex and in monkey and cat LGN may reflect the distribution of neurones responding to visual stimuli of many wavelengths (broad band cells). These are localized in the magnocellular layers of the monkey LGN[17–19] and in the A and A1 laminae and medial interlaminar nucleus[20,21] of the cat LGN regions stained by CAT 301. In the monkey visual cortex broad band cells[4] and CAT 301-positive cells are found in the CO-rich periodicities of layer III. Broad band cells may also be present in CO-rich bands of monkey area 18, which also coincide with CAT 301-positive patches (unpublished observations). CAT 301-positive cells are certainly not restricted to laminae in the LGN nor to layers in area 17 where broad band responses have been recorded, so their distributions in the visual system may be associated not only with broad band cells but also with other as yet unidentified cell colonies as well.

Previous studies with monoclonal antibodies to uncharacterized antigens have focused on classes of neurones identified by their morphology, connectivity and/or position in an organized structure[22–24]. The present and previous[9,10,25] reports demonstrate that CAT 301 recognizes surface molecules on many but not all neurones, not even those (for example, pyramidal cells) of the same morphological type. The nature of the neuronal surface molecule recognized by CAT 301 remains to be determined, as does the role of the molecule in the structure, function and development of the neurones it marks.

We thank Ms Bertha McClure for technical assistance. This study was supported by NIH USPHS grant NS10526.

Muscarinic inhibitory transmission in mammalian sympathetic ganglia mediated by increased potassium conductance

Alison E. Cole & Patricia Shinnick-Gallagher

Department of Pharmacology and Toxicology, University of Texas Medical Branch, Galveston, Texas 77550, USA

Slow muscarinic inhibition may be a powerful influence on membrane properties in the peripheral[1–3] and central nervous system[4]. But the location of the muscarinic receptors in sympathetic ganglia, either on interneurones or on the postganglionic membrane, and the underlying mechanism of the inhibitory response, remains controversial[5–7]. In mammalian sympathetic ganglia synaptic activation of muscarinic receptors located on inhibitory interneurones was thought to release catecholamines leading to a membrane hyperpolarization called the slow inhibitory postsynaptic potential, or s.-i.p.s.p.[8]. However, the s.-i.p.s.p. in parasympathetic ganglia[3,9,10] and in amphibian sympathetic ganglia[1,2] is due to direct monosynaptic activation of muscarinic receptors, accompanied by an increased potassium conductance (but see ref. 11), and is not mediated by catecholamines. The situation is less clear in mammalian sympathetic ganglia and monosynaptic s.-i.p.s.ps observed in other ganglia could be exceptions to the hypothesis. We showed earlier that the s.-i.p.s.p. in rabbit superior cervical ganglia is not affected by catecholamine antagonists[12]. We now show that the s.-i.p.s.p. in a mammalian sympathetic ganglion is due to the monosynaptic activation of muscarinic receptors, probably by an increase in potassium conductance.

The superior cervical ganglia along with their pre- and postganglionic nerves were isolated from adult male New Zealand rabbits and prepared as described previously[12]. Glass microelectrodes (30–100 MΩ) filled with 3 M KCl were used for intracellular recording from over 150 sympathetic neurones.

In all experiments, nicotinic responses were blocked by the administration of hexamethonium (500 μM) to facilitate examination of the s.-i.p.s.p. Iontophoretic application of acetylcholine (ACh, 2 M; 50–100 MΩ) elicited a hyperpolarization that mimicked the nerve-evoked s.-i.p.s.p. (40 Hz for 250 ms). Both responses were abolished by atropine (0.1 μM) but unaffected by the adrenergic antagonist phentolamine (1 μM) (Fig. 1). We previously showed with extracellular recordings that this concentration of phentolamine blocked hyperpolarizations induced by noradrenaline, adrenaline and

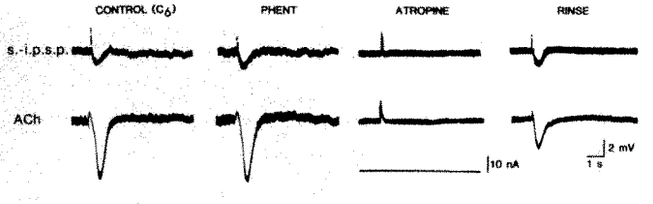

Fig. 1 Effect of antagonists on the nerve-evoked s.-i.p.s.p. and ACh hyperpolarization. Hexamethonium (C_6, 500 μM) eliminated all fast nicotinic responses leaving only the slow muscarinic responses. The s.-i.p.s.p. was elicited by orthodromic stimulation at 40 Hz for 250 ms; in the same cell, a single iontophoretic pulse of ACh was applied (50 nA, 40 ms). Phentolamine (1 μM) had no effect on either the s.-i.p.s.p. or ACh hyperpolarization, even after 30-min application. However, the muscarinic antagonist, atropine (0.1 μM) completely eliminated both responses. The responses returned after rinsing for 1 h. A representative current trace is positioned below the third ACh record. Membrane potential −62 mV.

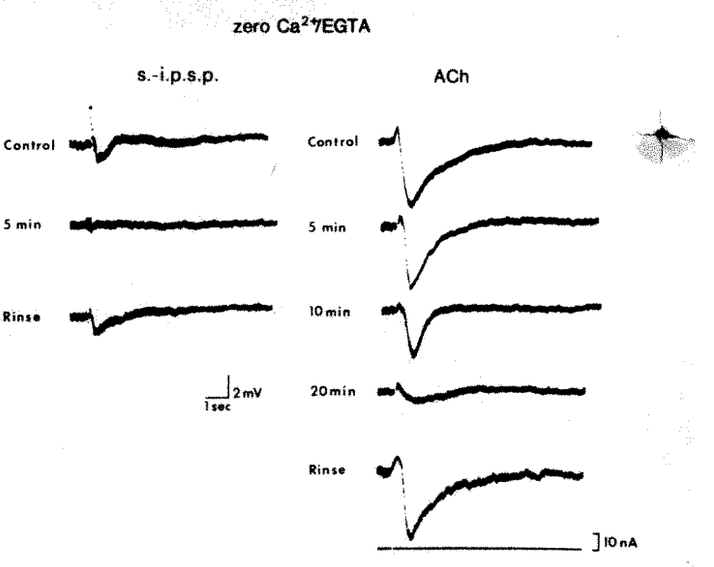

Fig. 2 Effect of blockade of synaptic transmission with 0 Ca^{2+}/EGTA solution on the nerve-evoked s.-i.p.s.p. and ACh hyperpolarization. The Ca^{2+}-free, high Mg^{2+} solution was prepared by substituting 2.5 mM $MgCl_2$ for $CaCl_2$ (3.7 mM $MgCl_2$, total); EGTA (1 mM) was also added. Both responses were recorded simultaneously from the same cell. Stimulation parameters are the same as in Fig. 1. The left-hand column shows the control s.-i.p.s.p., rapid block of the s.-i.p.s.p. in 0 Ca^{2+} solution and return of the response after rinse. The right-hand column shows that the simultaneously recorded ACh hyperpolarization was unchanged at the time when synaptic transmission was blocked (5 min). Prolonged exposure to the zero Ca^{2+} solution (20 min) eventually depressed the ACh response, possibly via a postsynaptic effect. Rinse records for both responses were recorded 20 min after return to control solution (10 and 20 min records in 0 Ca^{2+} media were omitted for the s.-i.p.s.p. as they were identical to the 5 min record). Membrane potential −60 mV.

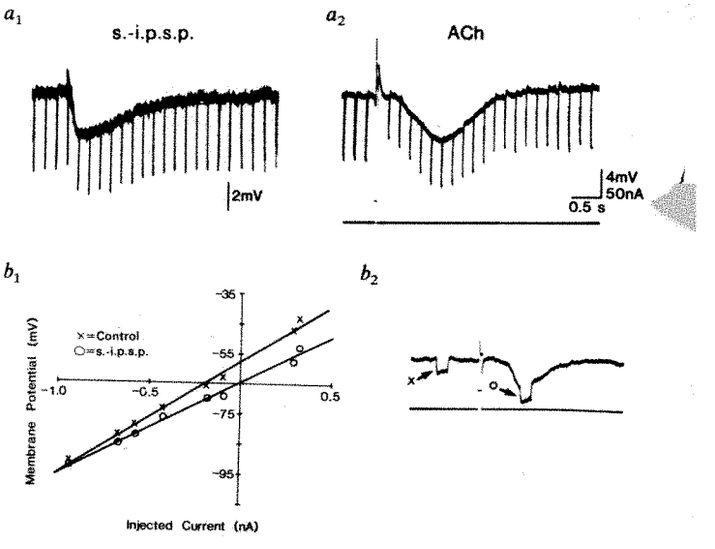

Fig. 3 Conductance changes during the s.-i.p.s.p. and ACh hyperpolarization (50 nA, 100 ms). *a*, Both responses were associated with a decrease in input resistance, reflected in the decrease in amplitude of the anodal constant current pulses. Current trace is located below the voltage trace for the ACh response. Time calibration is the same for both records. Membrane potential −55 mV. *b*, Current–voltage plot for the s.-i.p.s.p. Hyperpolarizing and depolarizing current pulses of constant duration (300 ms, see b_2) and varying amplitude were passed across the membrane before (×) and at the peak of the s.-i.p.s.p. (○). The difference in the slope of the two plots indicates a decrease in resistance during the s.-i.p.s.p. The intersection point of the lines represents the estimated reversal potential of the response, here, −94 mV. Membrane potential −58 mV.

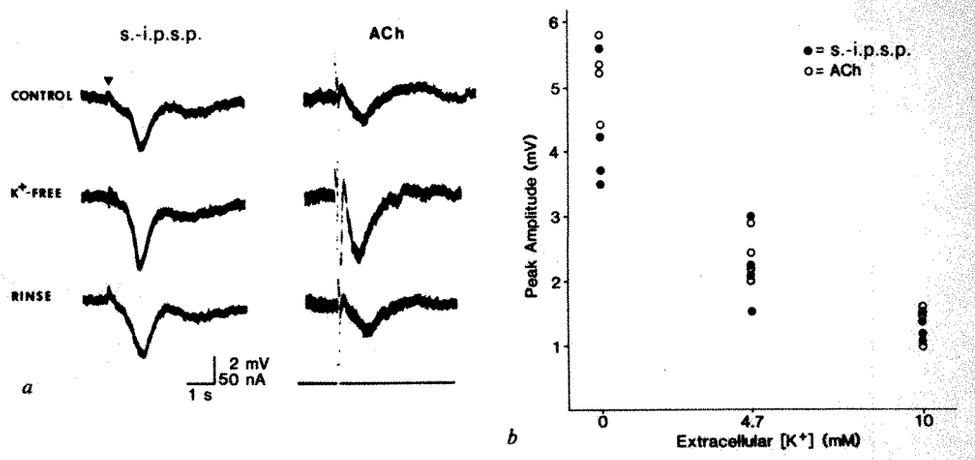

Fig. 4 Effect of extracellular K^+ concentration on the s.-i.p.s.p. and ACh hyperpolarization. *a*, Both the nerve-evoked s.-i.p.s.p. and hyperpolarization to a single iontophoretic pulse of ACh (40 nA, 100 ms) increased in amplitude when perfused with a K^+-free solution. Equimolar concentrations of NaCl were substituted for KCl in the physiological solution. Membrane potential −60 mV. *b* Illustrates the change in peak amplitude of s.-i.p.s.p. (×) and ACh hyperpolarization (○) versus extracellular K^+ concentration. Changing the K^+ concentration had no effect on the resting membrane potential of these cells.

dopamine[12]. These data suggested that catecholamines do not mediate the s.-i.p.s.p. in mammalian sympathetic ganglia.

To investigate whether the s.-i.p.s.ps are due to a disynaptic process, we tested the effect of blocking synaptic transmission on the response to iontophoretically applied ACh. Exposure to a 0 calcium/3.7 mM magnesium, EGTA (1 mM) solution quickly abolished the nerve-evoked s.-i.p.s.p. ($n = 3$, Fig. 2). In contrast, the ACh response persisted at a time when synaptic transmission was blocked, and was depressed only after prolonged exposure to the calcium-free solution (15 min) ($n = 8$). All responses returned to control levels during the rinse. Identical results were seen when synaptic release was blocked with tetrodotoxin (TTX, 1 μM; $n = 4$). After 3 min of superfusion with TTX, the s.-i.p.s.p. was eliminated while in the same four cells the ACh response was not affected. These data do not support the disynaptic hypothesis. In every case the ACh hyperpolarization persisted when synaptic transmission (that is, the s.-i.p.s.p.) was blocked. This suggests that the muscarinic action of ACh is a direct effect on the ganglion cells and the calcium-free solution may be affecting underlying ionic mechanisms at the postsynaptic membrane. This would explain the persistence and gradual depression of the ACh iontophoretic response long after transmitter release had been eliminated.

We examined the mechanism underlying the s.-i.p.s.p. and ACh hyperpolarization by passing constant current anodal pulses through the recording electrode during the responses to analyse the conductance changes (Fig. 3). In cells where both the s.-i.p.s.p. and ACh response were recorded at the same membrane potential ($n = 12$) (Fig. $3a_1$ and a_2) a small but consistent decrease in resistance was observed. These results reflect a similar increase in conductance during both the nerve-evoked s.-i.p.s.p. and the ACh hyperpolarization. In addition, current–voltage (I–V) plots were constructed by passing individual short duration current pulses across the membrane before and at the peak of the responses (Fig. $3b_2$). A series of anodal and cathodal current pulses of constant duration (200 ms) and varying amplitude (−1.5 to +1.0 nA) were passed through the recording electrode just before and at the peak of the hyperpolarization. Curves were plotted of current against absolute membrane potential. Typical plots for control resistance values (pre-response) and values at the peak of the s.-i.p.s.p. are shown in Fig. $3b_1$. A plot of the control resistance values against those values at the peak of the ACh hyperpolarization yielded similar results. The reversal potential estimated from the intersection of the current–voltage plots in the linear, non-rectifying part of the membrane[13] was 102.7 ± 10 ($n = 4$) for the s.-i.p.s.p. and 100.4 ± 11 ($n = 5$) for the ACh hyperpolarization. These experiments implied that potassium and/or chloride ions may be involved in the generation of the s.-i.p.s.p. Since the hyperpolarizations were not reversed when KCl electrodes were used, it is unlikely that chloride ions are responsible for the responses. From our evidence with zero calcium solutions, it appears that calcium ions may also be involved, although more conclusive evidence is necessary.

We compared the effects of changing the external potassium ion concentration on the ACh hyperpolarization and the s.-i.p.s.p. As shown in Fig. 4, removal of potassium from the superfusing solution increased the amplitude of both hyperpolarizing responses ($n = 9$). The response to iontophoretic ACh was increased $40 \pm 2\%$ and the s.-i.p.s.p. was increased $58 \pm 19\%$. There was no change in the duration of either potential. When the extracellular potassium concentration was elevated to 10 mM, both the ACh and s.-i.p.s.p. hyperpolarizations were depressed. The hyperpolarization to iontophoretically applied ACh decreased $25 \pm 2\%$ and the s.-i.p.s.p. by $39 \pm 4\%$. Figure 4*b* summarizes the changes in the s.-i.p.s.p. and ACh hyperpolarization as the extracellular potassium concentration was changed. This agrees with the hypothesis that the s.-i.p.s.p. and the ACh hyperpolarization which mimics it, are generated by an increased membrane conductance to potassium ions.

We report here the first evidence in a mammalian sympathetic ganglion that the s.-i.p.s.p. is mediated by an increased potassium conductance via monosynaptic activation of muscarinic receptors. Furthermore, the potassium current may be a calcium-activated potassium conductance, dependent on an influx of calcium ions, as suggested by the effect of zero calcium solution on both responses. Calcium-activated potassium conductances in a variety of nerve and muscle cells have been shown to mediate long-lasting hyperpolarizations following calcium influx[14–18]. In addition, calcium-activated potassium conductances have been linked to muscarinic responses in a number of neuronal systems[19,20]. These experiments provide further insight into the mechanisms of the muscarinic s.-i.p.s.p., a potential that may exert a powerful influence on membrane excitability and have an important role in the integration of autonomic function.

Specific depletion of immunoreactive growth hormone-releasing factor by monosodium glutamate in rat median eminence

B. Bloch*, N. Ling, R. Benoit, W. B. Wehrenberg & R. Guillemin

Laboratories for Neuroendocrinology, Salk Institute for Biological Studies, PO Box 85800, San Diego, California 92138, USA

A potent and specific growth hormone-releasing factor (GRF) was recently isolated and characterized from a human islet cell tumour of the pancreas that caused acromegaly[1–3]. Antibodies raised against the synthetic replicate of this peptide have allowed the immunohistochemical identification of GRF-producing neurones within the primate central nervous system[4]. Such neurones are found mainly in the arcuate nucleus[4–6] in human and monkey hypothalamus, suggesting that this nucleus is a primary source of GRF. We have further investigated this hypothesis by studying the anatomical organization of GRF neurones in rat hypothalamus, using an antibody raised against the recently characterized rat hypothalamic GRF[7] in normal animals and in animals neonatally treated with monosodium glutamate (MSG), a treatment which results in the selective destruction of arcuate nucleus neurones[8–10]. We present here the results which show that GRF-producing neurones are located mainly in the arcuate nucleus of rats. MSG treatment results in the complete loss of GRF- immunoreactive cell bodies within this nucleus and provokes a selective disappearance of GRF-immunoreactive fibres in the median eminence. These results show that the arcuate nucleus is the origin of the GRF-containing fibres that project to the median eminence and establish the MSG-treated rat as an *in vivo* model for studying growth hormone secretion in the absence of neurohumoral GRF.

Antisera against rat hypothalamic GRF were prepared by immunizing rabbits with a mixture of synthetic rat GRF and methylated bovine serum albumin emulsified in Freund's adjuvant as described previously[11]. Immunohistological studies were performed on tissue sections from 19 male rats of 3 and 11 months of age. Nine animals were either untreated or injected with saline and 10 animals were injected with MSG (4 g per kg subcutaneous, s.c.) on alternate days for the first 10 days of life[9]. This dose is known to produce an 80–90% loss of neuronal perikarya in the arcuate nucleus[8–10]. To increase peptide content in cell bodies, some rats received a colchicine injection (50 μg in 50 μl saline) in the lateral ventricle 48 or 72 h before they were killed. Brains were fixed by intracardial perfusion of anaesthetized animals (chloral hydrate, 3 mg per kg) with chilled 4% paraformaldehyde in 0.12 M phosphate buffer *p*H 7.2. The brains were cut into blocks and rinsed in phosphate buffer with increasing concentrations of sucrose (12–16%). Frontal sections 10–16-μm thick were prepared as described[4], mounted on gelatin-coated slides and stored at −20 °C until used. An indirect immunofluorescence technique was performed as described previously[4]; antibodies against rat GRF were used at a final dilution of 1 : 200 to 1 : 800. In addition, we used antibodies against ovine corticotropin-releasing factor (CRF), somatostatin and luteinizing hormone-releasing factor (LHRF) for comparative topographical studies. Controls for specificity of the immunostaining consisted of a comparison of adjacent sections treated with anti-GRF serum alone or with anti-GRF serum previously incubated with rat GRF (0.5 mg ml^{-1} undiluted antibody) or PHI or vasoactive intestinal peptide (up to 10 mg ml^{-1}), two peptides having considerable structural homology to rat GRF[7]. Only preincubation with synthetic rat GRF resulted in the disappearance of specific immunostaining.

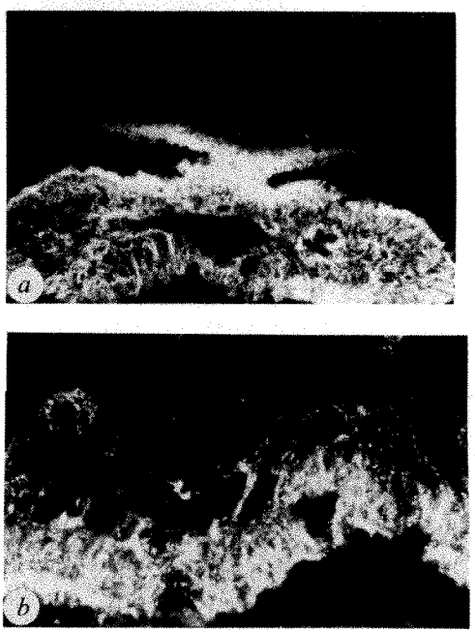

Fig. 1 Immunofluorescent staining of the median eminence of a normal adult rat with anti-rat GRF antiserum. *a*, General view of a frontal section of the posterior median eminence and the hypophyseal stalk, showing GRF-immunoreactive fibres in contact with the portal vessels. *b*, Higher magnification of a section stained with anti-rat GRF antiserum showing the course and termination of individual fibres.

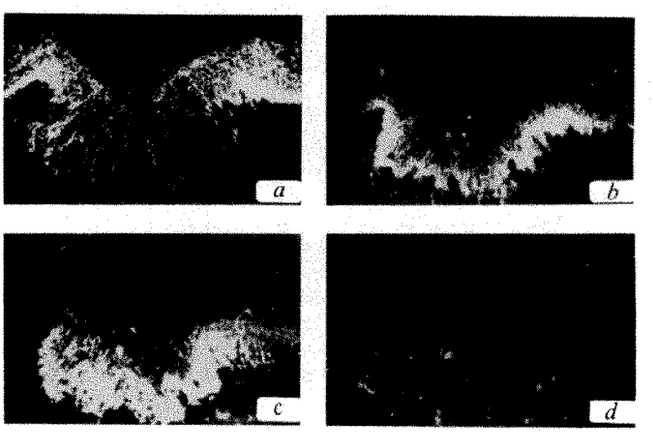

Fig. 2 Immunofluorescent staining of the median eminence of adult rats treated with monosodium glutamate (4 g per kg s.c.) on alternate days for the first 10 days of life. Immunoreactive fibres were observed in sections stained with anti-LHRF antiserum (*a*), anti-somatostatin antiserum (*b*) and anti-CRF antiserum (*c*) but were conspicuously absent from sections stained with anti-rat GRF antiserum (*d*).

In control rats, GRF immunoreactivity was constantly found in dense bundles of fibres in the median eminence, terminating in contact with portal vessels (Fig. 1), as well as in scattered fibres of the hypothalamus. No immunoreactive cell bodies were observed in animals not pretreated with colchicine. In rats pretreated with colchicine, numerous immunoreactive cells were found in the arcuate nucleus and the ventral and dorsolateral hypothalamus (Fig. 3), especially in the perifornical area and premammillary nuclei. Very few immunoreactive cell bodies were found in the ventromedial nucleus. In rats neonatally treated with MSG, the median eminence showed no GRF-immunoreactive fibres, while the distribution of LHRF-, somatostatin- and CRF-immunoreactive fibres was identical to that of control animals (Fig. 2). In the MSG-treated rats that received colchicine, GRF-immunoreactive cell bodies were only observed in the dorsolateral and ventral hypothalamus but not in the arcuate nucleus.

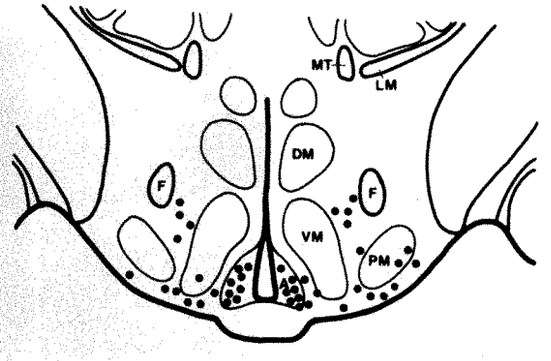

Fig. 3 Diagram of a frontal section of rat hypothalamus showing localization of GRF-immunoreactive cell bodies. A, arcuate nucleus; DM, dorsomedial nucleus; F, fornix; LM, medial lemniscus; MT, mamillothalamic tract; PM, ventral premamillary nucleus; VM, ventromedial nucleus.

Thus, the results obtained in normal rats show that the arcuate nucleus is the main source of GRF as has been found in man and monkey[4–6]. A very low abundance of neurones containing GRF immunoreactivity in the ventromedial nucleus of rats as well as primates suggests that this nucleus has a minor role in GRF production. This is in contrast to what has been hypothesized on the basis of electrical stimulation[12] and lesion experiments[13]. Since most of the GRF cell bodies are located in areas contiguous to the ventromedial nucleus, it is probable that the effects observed by destruction or stimulation of the ventromedial nucleus were due to extension of the lesion or diffusion of the stimulation to adjacent areas. Nevertheless, it cannot be excluded that neurones of the ventromedial nucleus might exert a direct stimulatory effect on GRF neuronal activity in the arcuate nucleus.

The disappearance of GRF immunoreactivity in the arcuate nucleus and median eminence after MSG treatment demonstrates that the arcuate nucleus is the source of the GRF fibres in the median eminence ending in contact with portal vessels. These results correlate well with the dramatic decrease of GRF bioactivity in the median eminence of MSG-treated rats reported by Acs *et al.*[14]. Actual quantification of this decrease must await the development of a radioimmunoassay for rat GRF. Although MSG treatment has been reported to result in a decrease in total pituitary growth hormone content in rats[15,16], pituitaries from such animals seem to have normal growth hormone secretion *in vitro*[17] and have a normal response to GRF *in vivo*[18]. Thus, the dramatic impairment of growth observed in MSG-treated rats must be related to the selective destructuion of the GRF neurones projecting in the median eminence, a conclusion supported by previous physiological studies[15]. The specificity of MSG in destroying GRF-containing neurones within the arcuate nucleus suggests that MSG-treated rats may serve as a useful *in vivo* model for the study of selective growth hormone deficiency of hypothalamic origin, an entity also observed in human neuroendocrinology[19].

Astrocytes present myelin basic protein to encephalitogenic T-cell lines

Adriano Fontana*, Walter Fierz & Hartmut Wekerle

Max-Planck-Gesellschaft, Clinical Research Unit for Multiple Sclerosis, Hermann- and Lilly-Schilling Foundation, Box 6120, D-8700 Würzburg, FRG

Astrocyte proliferation and perivascular lymphocyte infiltration are conspicuous among the cellular changes in the active brain lesions of multiple sclerosis patients[1]. Recent observations have indicated that most of the perivascular lymphocytes are T cells[2–4] which may be actively involved in the generation of the brain lesions. Much less is known about the significance of the proliferative astrocytes, although the fact that they produce an interleukin-1 (IL-1)-like factor that enhances the release of interleukin-2 by T lymphocytes[5,6], may provide a clue. We show here that rat astrocytes are able to present antigen to T lymphocytes in a specific manner which is restricted by the major histocompatibility complex (MHC) and that they can in particular activate myelin basic protein (BP)-specific, encephalitogenic T-cell lines. Only on such interaction do astrocytes express Ia antigens in easily detectable amounts. Antigen presentation by astrocytes may have a central role in the generation of immune responses in the brain.

T lymphocytes cannot recognize free antigen but are dependent on antigen presentation by accessory cells. This function, which is MHC-restricted and requires IL-1, has been attributed to macrophages[7–11] and more recently to dendritic cells[12–14]. In several studies accessory cell function has been found to be mediated also by other Ia-positive cells such as Langerhans cells of the skin and endothelial cells[15]. Here we evaluate astrocytes for their ability to present antigen.

Immune cytochemical studies using rabbit antisera against glial fibrillary acidic protein (GFAP), a defined astrocyte marker[16], revealed that astrocytes derived from newborn rats could be cultured to almost complete purity[17]. Such glial cell cultures were trypsinized after 3–4 weeks *in vitro*, and the cells plated on coverslips. Practically all of these cultured brain cells were GFAP-positive. In fact, if after trypsinization of glial cell cultures, the cells were plated on coverslips at a density of 2×10^5 cells, less than 20 cells per coverslip were found not to react with anti-GFAP antisera of three different sources (M. Schachner[18], A. F.[5] and Dakopatts Ltd). These results were considered to reflect the cell composition of the original cultures, as in non-confluent monolayers quantification of GFAP-negative cells was possible and during the staining procedure with anti-GFAP antibodies no loss of cells was observed. The cultures were also studied by indirect immunofluorescence using antibodies against galactocerebroside[19], the major glycolipid in myelin, which is thought to be a specific cell-surface marker for oligodendrocytes[20,21]. No galactocerebroside-positive cells were seen in our cultures. To exclude contamination by microglia cells/macrophages, the amount of cells with receptors for the Fc portion of immunoglobulin was determined using the techniques of Raff *et al.*[20]. A small amount of positive cells with a vacuolar labelling pattern due to ingested fluorescein isothiocyanate (FITC)-conjugated immunoglobulin–anti-immunoglobulin complexes became detectable in primary

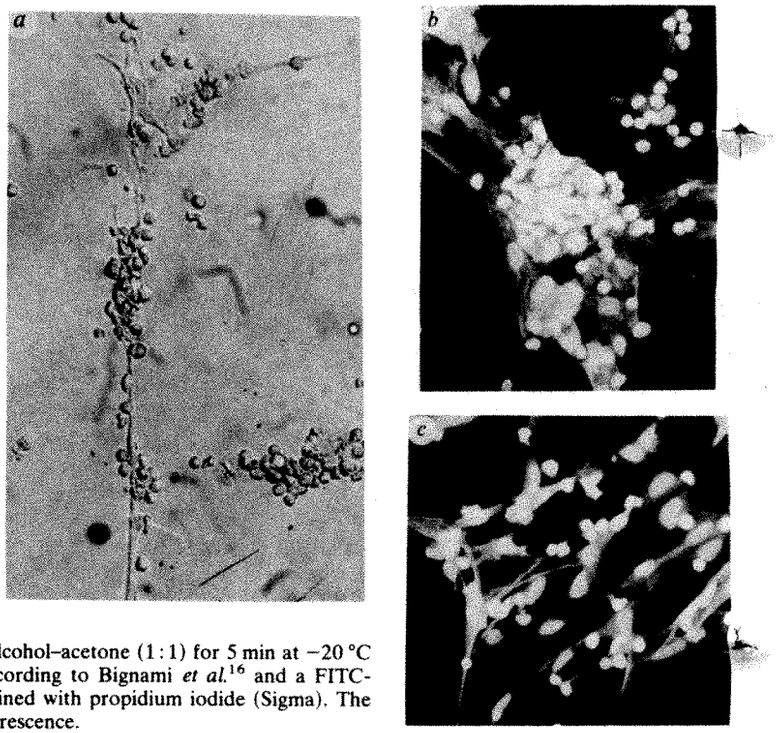

Fig. 1 *a*, The attachment of BP-specific Lewis T cells to Lewis astrocytes in the presence of soluble BP. *b*, *c*, Astrocytes with large, oval nuclei and GFAP-positive processes and cytoplasmic filaments; in contrast, the nuclei of T cells appear smaller, round and intensely fluorescent. *b* Shows tight clusters of BP-specific Lewis, T cells on Lewis astrocytes in the presence of BP. In control cultures of astrocytes of the MHC-congenic L.BN origin treated with BP, the T cells are randomly distributed and unblasted (*c*). **Methods:** For astrocyte cultures, brains of newborn rats (Lewis, L.BN or (Lewis × BN)F_1) were dissociated according to the method of Manthorpe *et al.*[17]. After trypsinization, 10^6 brain cells were plated in 5 ml glial culture medium (Dulbecco's modified Eagle medium (DMEM) supplemented with 10% fetal calf serum (FCS) and 300 μg ml^{-1} L-glutamine) in 25-cm^2 tissue culture flasks. Medium was changed on alternate days. After 3–4 weeks, the flasks were vigorously shaken by hand (see ref. 34), the detached cells discarded and the monolayer was washed three times. After this procedure the monolayer was trypsinized, the cells were reseeded on coverslips and allowed to adhere and spread for 2 days. Then BP- or OVA-specific Lewis cells and the corresponding antigen (BP or OVA) were added and cultured for 3–6 days. Direct interactions between T cells and astrocytes were studied by bright-field microscopy. To demonstrate the astrocyte-specific glial fibrillary acidic protein (GFAP), the cells on the glass slides were immersed in phosphate-buffered saline, dried, fixed in alcohol–acetone (1 : 1) for 5 min at −20 °C and stained with rabbit antisera against GFAP prepared according to Bignami *et al.*[16] and a FITC-conjugated goat anti-rabbit IgG. Cell nuclei were counterstained with propidium iodide (Sigma). The slides were examined for green (GFAP) and red (nuclei) fluorescence.

cultures but disappeared completely after passaging by trypsinization and reseeding of the astrocytes. The same picture emerged when testing a monoclonal antibody (W3/25) which stains both rat helper T cells and macrophages[22]. Cells of passaged astrocyte cultures did not label with anti-W3/25.

To test antigen presentation, graded amounts of passaged astrocytes were co-cultivated with cells of permanent BP-specific T-lymphocyte lines. These T-cell lines were originally derived from lymph node cells of rats immunized with BP[23]. They are kept in long-term culture by repeated restimulation with BP in the presence of irradiated normal syngeneic thymus cells as accessory cells and by T-cell growth factor-dependent expansion between the restimulations. They express the 'helper' cell phenotype (W3/25+)[24]. Within 24 h of culture in the presence of BP, BP-specific T cells of Lewis rat origin (L-BP) adhered tightly to the syngeneic astrocytes and formed aggregates of 10 and more lymphocytes per astrocyte (Fig. 1*a*). Within 48–72 h of culture, the adherent T cells transformed to large activated blast cells. This interaction was immune-specific: when ovalbumin (OVA) instead of BP was added to L-BP–astrocyte cultures, the T cells were randomly distributed, with no signs of physical contact with the astrocytes during observation periods of up to 72 h. Moreover, T-cell–astrocyte complexes were not formed when L-BP T cells were cultured in the presence of BP with MHC-congeneic L.BN astrocytes. The population of brain cells binding antigen-specific syngeneic T cells was identified as astrocytes by using GFAP as a marker (Fig. 1*b*, *c*). In either antigen or MHC-incompatible cell systems T lymphocytes remained in the state of small resting cells.

Table 1 Ia expression by astrocytes after specific interaction with T cells

Astrocyte treatment	Anti-Ia staining pattern of astrocytes of Lewis rats	L.BN rats
Con A	–	–
L-BP + BP	OX6, OX3 HL	–
L-BP + Con A	OX6, OX3 HL	OX6

BP-specific cells of Lewis rat origin (L-BP) were co-cultured with astrocytes and BP or Con A (5 μg ml^{-1}). Astrocyte cultures were double stained with anti-Ia monoclonal antibodies and anti-GFAP antiserum as described in Fig. 3 legend. Two anti-Ia antisera were used, the OX6 being an anti-Ia common determinant and the OX3 HL an anti-polymorphic determinant (Lewis-specific)[33]. –, No reactivity; OX6 or OX3 HL, positive staining of astrocytes with the anti-Ia antiserum OX6 or OX3 HL (Sera-Labs).

Morphological activation of astrocyte-associated T-cell lines resulted in their rapid proliferation. This was quantified by culturing T cells in the presence of both antigen and irradiated astrocytes and measuring ^{3}H-thymidine uptake. As a positive control, thymus was used as an optimal source of accessory cells. The results confirmed the microscopic observation. As shown in Fig. 2*a*, when L-BP T cells were cultured with astrocytes of Lewis rat origin in the presence of BP, ^{3}H-thymidine incorporation was highly elevated. The response was dependent on the number of astrocytes, with astrocyte-to-responder ratios lower than one. The response of L-BP T cells was dependent on the specific antigen BP, as no proliferation was observed when, as an irrelevant antigen, OVA was added to the T cells instead of BP (Fig. 2*a*). On the other hand, OVA was highly immunogenic to an OVA-specific Lewis T-cell line, when presented by Lewis astrocytes. The incorporation of ^{3}H-thymidine by 10^4 OVA-treated T cells was 33 ± 7 c.p.m. and in the presence of 10^4 irradiated syngeneic astrocytes 9,859 ± 2,469 c.p.m. These experiments demonstrate antigen specificity of astrocyte-dependent T-cell proliferation.

Antigen presentation by astrocytes was restricted by the MHC. In the presence of BP, significant incorporation of ^{3}H-thymidine by 10^4 responder L-BP T cells was produced by syngeneic Lewis rat astrocytes and astrocytes from (Lewis × BN)F_1 hybrids (Fig. 2*b*). No response was observed in the presence of MHC-congeneic L.BN astrocytes. These L.BN astrocytes, however, functioned perfectly well as accessory cells when added to a BP-specific T-cell line from a (Lewis × BN)F_1 rat (data not shown).

There is ample evidence that Ia antigens expressed by antigen-presenting cells regulate immune responsiveness in concert with the Ia-restricted T-cell receptor[25]. So far, Ia antigens have been found on cells having accessory function such as macrophages and dendritic cells. The MHC-restricted astrocyte-mediated activation of T helper lymphocytes would require the presence of Ia antigens on astrocytes also. It has been shown that the antigen recognition by our T-cell lines is only possible in the context of Ia antigen on the presenting cells, as evidenced by restriction experiments (E. Günther *et al.*, in preparation),

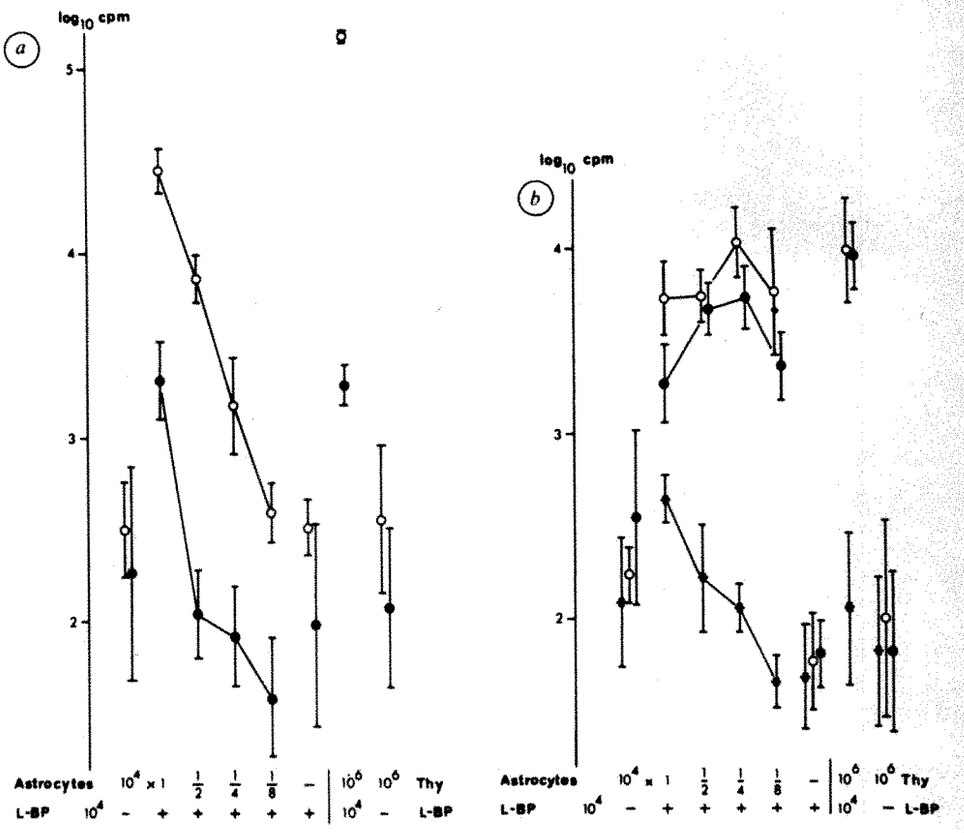

Fig. 2 *a*, L-BP T cells co-cultured with Lewis astrocytes or Lewis thymus cells in the presence of BP (○) or OVA (●). *b*, L-BP T cells added in the presence of BP to astrocytes or thymus cells of Lewis (○), L.BN (*) or (Lewis×BN)F_1 (●) origin. Data are given as $\log_{10}$ c.p.m. of ^{3}H-thymidine incorporation ±95% confidence limits.
Methods: BP-specific Lewis T-cell lines (L-BP) were prepared according to the method of Ben-Nun *et al.*[23]. Astrocytes were prepared as described in Fig. 1 legend, irradiated (3,000 rad) and co-cultured in quadruplicate in round-bottomed microtitre wells (0.2 ml) with L-BP T cells in the indicated concentrations. As a positive control, 10^6 irradiated thymus cells were used instead of astrocytes. The medium consisted of DMEM supplemented with 1% Lewis rat serum L-glutamine (300 μg ml^{-1}), L-asparagine (36 μg ml^{-1}) and indomethacin (1 μg ml^{-1}). ^{3}H-thymidine was added (0.2 μCi per well, specific activity 2 Ci mmol^{-1}) after 48 h of culture and cells were collected after another 14 h.

blocking experiments and adaptation of Ia from presenter cells by T-cell line during activation (H.W., in preparation). We have been unable to demonstrate Ia antigens on cultured naive astrocytes with anti-Ia antisera, but this does not exclude the possibility that a low concentration of functionally active Ia molecules is present. More important, however, we could demonstrate the expression of Ia antigens by astrocytes after specific contact with T lymphocytes (Table 1, Fig. 3). The induced Ia antigens were expressed by astrocytes as shown by double staining with anti-Ia and anti-GFAP antisera (Fig. 3) and by the phenotype of the expressed Ia following the genotype of the astrocytes rather than that of the lymphocytes. The allogeneic activation of the Lewis T-cell line L-BP by L.BN astrocytes and concanavalin A (Con A), which overrules MHC restriction, induced Ia antigens on GFAP-positive cells, which carried the non-Lewis phenotype (Table 1). The induction of Ia expression by astrocytes after specific contact with T lymphocytes, and perhaps also after other stimuli, could explain the controversial results of recent immune histological studies on Ia expression in mouse brain[26,27]. On human glioblastoma cells binding assays clearly revealed HLA-DR determinants[28].

Other investigators have shown that an Ia-positive subpopulation of macrophages and/or the dendritic cells are most active in antigen presentation[7–14]. Contamination of astrocyte cultures with dendritic cells is unlikely, as, in contrast to astrocytes, the rat dendritic cell is a nonadherent cell. Furthermore, it has been demonstrated in the rat that dendritic cells are widely distributed in the interstitial connective tissues (for example spleen, liver, skin) but have not been found in brain. At least a proportion of GFAP-negative cells detected in our cultures (0.01%) could represent macrophages. Using different techniques it was found that the non-passaged primary brain cell cultures contained small amounts of macrophages, while contamination with macrophages was not observed in the passaged cultures used for the T-cell proliferation assay. However, trace amounts of undetected contaminating macrophages or dendritic cells could be a possible source of error in our experiments. We regard this theoretical possibility as very unlikely. Evidence supporting the antigen-presenting function of astrocytes are both the finding of a MHC-restricted and antigen-specific physical contact observed between the astrocytes and the T cells, as well as the induction of Ia antigen expression by astrocytes exposed to activated T cells. In addition, previous studies showing the release of IL-1-like factors by mouse astrocytes stimulated with endotoxin[5], rat C6 glioma cells[6], rat primary astrocyte cultures (A.F., unpublished observation) and human glioblastoma cells[29] further substantiate the hypothesis that astrocytes are active accessory cells.

Fig. 3 To demonstrate Ia antigens, Lewis astrocytes were co-cultured with syngeneic BP-specific T cells and BP in round-bottomed microtitre wells as described in Fig. 2 legend. After 3 or 6 days of culture, cells were removed from the microtitre wells and stained with monoclonal anti-Ia antibodies[33] and rhodamine-conjugated rabbit anti-mouse immunoglobulin. Smears of stained cells were dried, fixed and stained for GFAP as described in Fig. 1 legend. The cells were examined for red fluorescence demonstrating cell-surface Ia antigens (*a*) and green fluorescence demonstrating intracellular GFAP (*b*). The relatively globular form of the astrocyte without long processes results from the incubation condition in the round-bottomed microtitre well where astrocytes in the cell pellet are prevented from adherence and spreading.

The role of astrocytes as accessory cells could be of primary importance in presenting cerebral antigens to infiltrating lymphocytes within inflammatory lesions of brains from patients with multiple sclerosis. This, and the finding that astrocytes themselves can be activated by factors released from stimulated lymphocytes[30], may connect two morphological hallmarks of the active multiple sclerosis lesion, that is, T-cell infiltration and astrocyte proliferation[1]. More generally, astrocytes may have a previously unrecognized physiological cell function pivotal to the generation of immune responses within the brain tissue. The central nervous system has been considered to be an immunologically privileged site as it lacks a lymphatic drainage and is shielded from the blood by the blood–brain barrier. At the site of this barrier an intense contact has been observed between astrocytes and the brain vascular tissue[1,31], and therefore an active contact between the immune system and the brain may directly depend on astrocyte function. Whether the accessory cell function of astrocytes is applicable to all or only a subpopulation of astrocytes such as process bearing type II cells (see ref. 32) remains to be determined.

We thank Miss P. Bourquin, Mrs R. Röhrig and Mrs E. Weber for technical assistance, Dr M. Schachner for gifts of anti-GFAP antisera and Dr Bologa-Sandru for anti-galactocerebroside antisera. The project was in part supported by the Swiss NSF (project no. 3.938–0.82) (to A.F.).

Hydroxyl radical scavengers inhibit human natural killer cell activity

Manikkam Suthanthiran, Scott D. Solomon, Perry S. Williams, Albert L. Rubin, Abraham Novogrodsky & Kurt H. Stenzel

Departments of Biochemistry and Medicine, The Rogosin Kidney Center, Cornell University Medical College, 1300 York Avenue, New York, New York 10021, USA

As natural killer (NK) cell activity is an essential constituent of host defence systems[1] and reactive oxygen intermediates participate in such defence[2–4], the effect of scavengers of oxygen radicals on NK cell activity was investigated. Hydroxyl radical ($OH^{\cdot}$) scavengers[5] (dimethyl sulphoxide (DMSO), thiourea, dimethylurea, tetramethylurea, benzoic acid, ethanol, methanol and ethylene glycol) inhibited NK cell activity. Catalase, a scavenger of H_2O_2, and superoxide dismutase (SOD), a scavenger of O_2^-, either alone or in combination, did not inhibit NK cell activity. Inhibition of the lipoxygenase pathway of arachidonic acid metabolism, a potential source of cellular $OH^{\cdot}$, with nordihydroguaiaretic acid[6] and 5,8,11,14-eicosatetraynoic acid (ETYA)[7] resulted in marked inhibition of NK cell activity. Inhibition of the cyclooxygenase pathway[7,8] with acetylsalicylic acid or indomethacin had minimal effects on NK cell activity. Taken together, these findings suggest that $OH^{\cdot}$, possibly generated via the lipoxygenase pathway of arachidonic acid metabolism, is critical for NK cell cytotoxicity.

NK cell activity is inhibited by a variety of structurally unrelated compounds that all share the property of being able to scavenge $OH^{\cdot}$ (Fig. 1). Statistically significant inhibition of NK cell activity mediated by large granular lymphocytes (LGL), which are the principal NK cells in peripheral blood, with MOLT-4 as target cells is shown in Fig. 1*a*, and with K-562 as target cells in Fig. 1*b*. Urea, which is structurally related to thiourea, tetramethylurea and dimethylurea, but is not an $OH^{\cdot}$ scavenger, did not inhibit NK cell activity even at 50 mM concentration. Other $OH^{\cdot}$ scavengers, such as ethanol, methanol and ethylene glycol, also mediated inhibition of NK cell activity. The alcohols are relatively less efficient scavengers[5] of $OH^{\cdot}$ and inhibition of NK cell activity required higher concentrations than for the other agents. Fifty per cent inhibition of NK cell activity was observed with LGL as effector cells and MOLT-4 or K-562 as target cells with the addition of methanol (315 mM), ethanol (80 mM) and ethylene glycol (320 mM) to the NK test system. None of the $OH^{\cdot}$ scavengers affected the binding capacity of LGL to target cells at concentrations that resulted in significant inhibition of NK cell activity as tested in the target cell-binding assay[9]. The target cell-binding assay was performed by incubating LGL with MOLT-4 or K562 at an effector to target ratio of 1:1. LGL (1×10^6 cells ml^{-1}) were incubated with target cells (1×10^6 cells ml^{-1}) for 30 min at 4 °C with or without various $OH^{\cdot}$ scavengers. The cells were then resuspended and a minimum of 200 effector cells were counted in a Neubaur Counting Chamber covered with an acridine orange-coated coverslip with a simultaneous UV light and phase contrast illumination to determine the number of effector–target conjugates. The use of acridine orange-coated coverslips and UV light[10] allowed us to clearly distinguish between effector and target cells.

The addition of Me_2SO (75 mM), thiourea (10 mM), tetramethylurea (10 mM), dimethylurea (25 mM), benzoic acid (10 mM), ethylene glycol (320 mM), ethanol (80 mM) and methanol (315 mM) to the NK test system did not result in significant alterations in the number of effector–target conjugates formed. Twenty-five–40% of LGL formed conjugates with the target cells in the presence or absence of $OH^{\cdot}$ scavengers.

Nonspecific toxicity of agents used as $OH^{\cdot}$ scavengers may reasonably be excluded as an explanation for their inhibition of NK cell activity as target cells released less ^{51}Cr in the presence of the $OH^{\cdot}$ scavengers. Several additional experiments were performed to exclude further the possibility that nonspecific toxic effects of $OH^{\cdot}$ scavengers were responsible for the inhibition. First, none of the $OH^{\cdot}$ scavengers affected the viability of LGL, as determined by Trypan blue exclusion at concentrations that mediated significant inhibition of NK cell activity (Table 1, protocol 1). Second, LGL pretreated with DMSO (150 mM), thiourea (50 mM) and tetramethylurea (25 mM) and subsequently washed before being used as effector cells, exhibited normal NK cell activity (Table 1, protocol 2). The third and perhaps most compelling evidence against nonspecific toxicity

0028–0836/84/030276—03$01.00

Table 1 Lack of nonspecific toxicity of OH· scavengers

Protocol	DMSO (150)	Thiourea (50)	OH· scavenger (mM) Ethylene glycol (320)	Methanol (630)	Tetramethylurea (25)
(1) Cell viability	100 (3)	100 (3)	100 (3)	100 (3)	100 (3)
(2) Pretreatment	130 ± 10 (4)	113 ± 9 (4)	ND	ND	125 ± 13 (4)
(3) Antibody-dependent cell-mediated cytotoxicity	103 ± 6 (6)	87 ± 9 (10)	81 ± 8 (3)	86 ± 5 (3)	ND

Protocol 1: Cell viability was determined using a Trypan blue exclusion assay. Per cent of viable cells found in three experiments is shown. *Protocol 2*: Large granular lymphocytes were incubated with OH· scavengers for 3 h at 37 °C, washed three times with PBS, then used as effector cells with MOLT-4 as target cells. Results are expressed as per cent specific ^{51}Cr release found with untreated LGL as effector cells. *Protocol 3*: Antibody-dependent cell-mediated cytotoxicity (ADCC) was determined with peripheral blood mononuclear cells as effector cells, and antibody-coated chicken red blood cells as target cells in a 3-h ^{51}Cr release assay[23] (effector:target ratio is 5:1). Results are expressed as per cent specific ^{51}Cr release found in OH· scavenger-free ADCC. Values shown are % of control value (mean ± s.e.) with the number of experiments given in parentheses. ND, not determined.

of OH· scavengers is our finding of intact antibody-dependent cell-mediated cytotoxicity (ADCC) activity in the presence of DMSO (150 mM), thiourea (50 mM), ethylene glycol (320 mM) or methanol (630 mM) (Table 1, protocol 3). The alterations in NK cell activity found with preincubation of LGL with OH· scavengers (protocol 2) and the effect of OH· scavengers on ADCC (protocol 3) were not significant by Student's *t*-test for two means. Another argument against a nonspecific toxicity of OH· scavengers is our earlier finding of intact phytohaemagglutinin (PHA) and concanavalin A (Con A)-induced mitogenesis of human peripheral blood mononuclear cells in the presence of OH· scavengers at concentrations that resulted in the inhibition of NK cell activity[11].

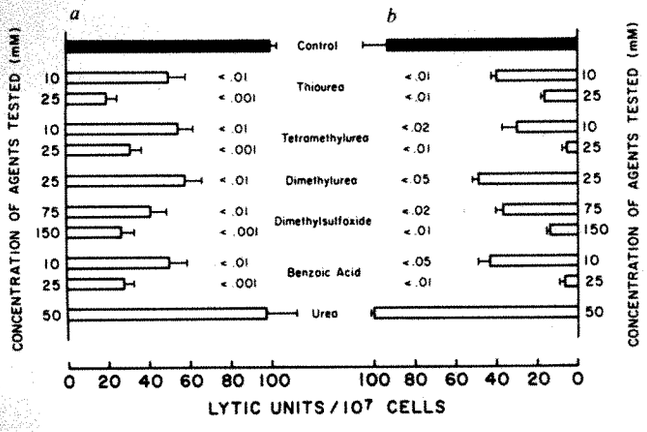

Fig. 1 Inhibition of NK cell activity by OH· scavengers. Large granular lymphocytes (LGL) isolated from the non-adherent fractions of peripheral blood mononuclear cells by centrifugation on a discontinuous Percoll density gradient by the method of Timonen and Saksela[24] were used as effector cells. Adherent cell contaminating peripheral blood mononuclear cells were removed by passage over a Sephadex G-10 column as described previously[25]. The NK cell preparations contained 0.1% monocytes or polymorphonuclear leukocytes as determined by nonspecific esterase staining[26] or by scoring LGL in a Neubaur Counting Chamber covered with an acridine orange-coated coverslip with simultaneous UV light and phase contrast illumination[10]. Cell lines, MOLT-4 or K-562, maintained as suspension cultures, were labelled with ^{51}Cr and used as target cells in a 3-h ^{51}Cr release assay[23]. The per cent specific release (SCR) was calculated by the formula:

$$\frac{\text{experimental counts} - \text{spontaneous counts}}{\text{maximum counts}} \times 100$$

The cytotoxicity assay was established at multiple effector:target ratios and dose–response curves were generated by plotting per cent SCR versus the number of effector cells to compute lytic units. The number of effector cells needed to lyse 30% of the target cells was designated as one lytic unit. The effect of OH· scavengers on NK cell activity was determined by adding various agents, at concentrations shown, to the cytotoxicity assay. Results are mean (±s.e.) of four experiments with MOLT-4 as target cells (*a*) and results of three experiments with K-562 as target cells (*b*). Statistical significance of inhibition mediated by OH· scavengers was determined using Student's *t*-test for two means.

A potential source of OH· is the univalent reduction of molecular oxygen. In the monovalent pathway of oxygen reduction, superoxide anion (O_2^-) is produced first, followed by the formation of hydrogen peroxide[12]. O_2^- can interact with H_2O_2 to form OH·, as originally proposed by Haber and Weiss[13]. As O_2^- and H_2O_2 can serve as precursors of OH·, we examined the effect of SOD, a scavenger of O_2^-, and catalase, a scavenger of H_2O_2, on NK cell activity. The results obtained by adding catalase (1,000 and 5,000 units ml^{-1}) or SOD (50 and 250 μg ml^{-1}), or catalase (5,000 units ml^{-1}) plus SOD (250 μg ml^{-1}) to the NK test system are summarized in Fig. 2. Catalase and SOD did not inhibit NK activity either alone or in combination. The inability of catalase to inhibit NK activity agrees with previous reports[14]. The lack of inhibitory effect of SOD on NK activity, however, does not support the findings of Roder *et al.*[14], that SOD inhibited NK activity mediated by LGL using K-562 as target cells. In multiple experiments, we found that SOD, over a wide range of concentrations (50–250 μg ml^{-1}), failed to inhibit NK cell activity mediated by peripheral blood mononuclear cells, the non-adherent fraction of peripheral blood mononuclear cells or LGL, using either K-562 or MOLT-4 as target cells, in our experimental conditions.

The finding that OH· scavengers inhibit NK cell activity, while scavengers of O_2^- and H_2O_2 (potential precursors of OH·) do not, suggests several possibilities. First, OH· might be generated at the interplasma membrane space between the effector and target cells and catalase or SOD might not gain access to this space. Second, OH· might be generated at an intracellular site;

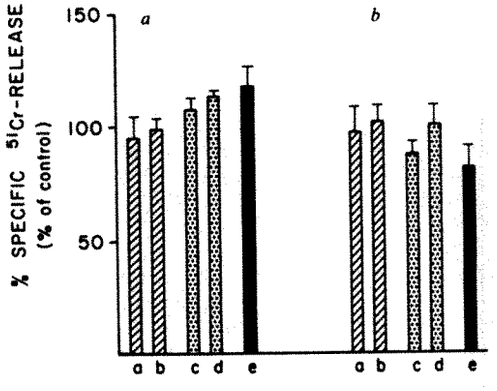

Fig. 2 Effect of catalase or SOD on human NK cell activity. *a*, Results of three experiments (mean ± s.e.) with LGL as effector cells and MOLT-4 as target cells. *b*, Results of five experiments with K-562 target cells. Effector:target ratio 25:1. a and b: catalase 1,000 and 5,000 units ml^{-1} respectively; c and d: SOD 50 and 250 μg/ml respectively; e: catalase 5,000 units ml^{-1} + SOD 250 μg ml^{-1}.) Per cent of SCR without catalase or SOD (100% values) was 43 ± 2% with MOLT-4 as target cells and 38 ± 4% with K-562 as target cells.

Table 2 Effect of inhibitors of arachidonic acid metabolism on NK cell activity

Agent tested	Concentration (μm)	Target cells: K-562 Lytic units per 10^7 cells	P	Target cells: Molt-4 Lytic units per 10^7 cells	P

Acetylsalicylic acid	1,000	135±17	NS	73±9	NS

LGL functioned as effector cells and ^{51}Cr-labelled K-562 or MOLT-4 were used as target cells. Inhibitors of arachidonic acid metabolism were added, at concentrations shown, to the NK test system. Lytic units were calculated as described in Fig. 1 legend. Results (mean±s.e.) of three experiments. *P* determined by Student's *t*-test for two means. NS, not significant; ND, not determined.

a site that is also inaccessible to catalase or SOD. Third, $OH^{\cdot}$ might also be generated during arachidonic acid metabolism[15]. Besides being the source of $OH^{\cdot}$, additional interactions between $OH^{\cdot}$ and arachidonic acid can also be envisioned. Specifically, arachidonate may be oxidized by $OH^{\cdot}$ and the resulting metabolic products might be responsible for the cytolytic activity of NK cells. The findings that phospholipase A_2 is activated during human NK cell cytotoxicity[16] and that horse eosinophil degranulation might depend on calcium-induced activation of phospholipase A_2 and generation of lipoxygenase products of arachidonic acid metabolism[17], lend credence to the latter hypothesis. As arachidonic acid metabolism might be involved in NK cell activity either as a source of oxygen-centred radicals or of their metabolic products, either directly or indirectly, the effect of various inhibitors of arachidonic acid metabolism on NK cell activity was investigated. Nondihydroguaiaretic acid (NDGA), an inhibitor of the lipoxygenase pathway of arachidonic acid metabolism, and ETYA which inhibits both cyclooxygenase and lipoxygenase pathways, mediated significant inhibition of NK cell activity (Table 2). In contrast, acetylsalicylic acid and indomethacin, which inhibit the cyclooxygenase pathway, failed to mediate significant inhibition of NK activity.

How might $OH^{\cdot}$ participate in NK cell activity of LGL? The possibility that $OH^{\cdot}$ contributes directly to target cell lysis by being generated at the interplasma membrane space between target cells and effector cells cannot be rigorously excluded. However, involvement of $OH^{\cdot}$ in earlier steps in the sequence of events leading to target cell lysis seems more likely. This latter notion is supported by the findings of defective NK cell activity in Chediak-Higashi patients, whose cells generate reactive oxygen intermediates in response to NK-susceptible targets[14] but are inefficient as NK cells, suggesting that free radical generation alone might not be sufficient to mediate cytotoxicity. In the context of a 'stimulus–secretion' model for NK cell activity[9,18,19], and in view of evidence that lysosomal enzymes may be the actual lytic moiety[1,9,18], $OH^{\cdot}$ participation may be via release of potent lysosomal enzymes either by direct lysosomal membrane peroxidation[20] or by a cyclic nucleotide-regulated mechanism[21,22]. Alternatively, $OH^{\cdot}$ might also participate in NK cell cytotoxicity via lipoxygenase pathway products. Clearly, further work is required to elucidate the role of $OH^{\cdot}$ in the complex biochemical mechanisms leading to target cell lysis in the NK cell system. It is already clear, however, that $OH^{\cdot}$ or a closely related species of free radical is involved in the metabolic programme pertinent to acquisition of lytic potential by NK cells.

We thank Ms Monica Evelyn and Ms Regina Vogel for technical assistance and Ms Ann Seton and Ms Jennifer Stenzel for secretarial help in the preparation of this manuscript. This work was supported in part by Sylvan League Fund and by Helena Rubinstein and Talisman Foundation.

Viral perturbation of endocrine function: disordered cell function leads to disturbed homeostasis and disease

Virus-induced disease occurs both through direct destruction of cells by viruses and/or secondarily through lysis of infected cells by immunological assault[1–5]. We asked whether viruses could also cause injury and disease by altering the cell's normal or expected functions without destroying the cells. Here we show that a relatively noncytopathic virus can perturb endocrine functions by disordering the synthesis of a hormone needed for growth and glucose regulation, while replicating in a specialized cell making that hormone. Yet, despite viral replication and alteration in synthesis of the specialized cell's homeostatic product, the infected cell remains free from structural injury.

0028–0836/84/030278—04$01.00

Newborn C3H/St, C3H/HeJ, C57Br/cdj, CBA/N, AKR/J and BALB/kae nude mice infected with 60 plaque-forming units (PFU) of lymphocytic choriomeningitis virus (LCMV) Armstrong strain 1371 had clear-cut developmental retardation manifested as decreases in body weight and length[6] that became evident as early as 5 to 7 days after viral inoculation. Pituitaries from infected mice had viral antigens but were structurally normal (Fig. 1*A*). Despite the presence of viruses in these cells, there was no evidence of altered anatomy, cell lysis or inflammatory infiltrates by low power microscopy; high resolution microscopy showed normal cell morphology and structure[7,8].

Using monoclonal antibodies[9] directed against LCMV polypeptides, we demonstrated the restriction of viral replication to the pituitary glands' anterior lobe (Fig. 1*B*). Application of a two-fluorochrome system[10] designed to stain LCMV nucleoprotein with one dye and either growth hormone (GH) or prolactin (PL) with the other revealed LCMV replicating primarily in those cells that made GH and not in cells making PL (Fig. 1*C–G*). Other studies showed that LCMV did not replicate in cells making thyroid stimulating hormone or adrenocorticotrophic hormone[7,8].

The two major activities of GH are regulation of growth and glucose metabolism[11,12]. Accordingly, mice persistently infected with LCMV ARM 1371 underwent significant decreases in body length and weight and became defective in glucose metabolism (Table 1, Fig. 2). Simultaneously, GH levels diminished in pituitary glands of infected mice, but PL levels remained normal. Serum contains insulin-like growth factors (IGFs) at concentrations dependent on GH[13]. Measurement of IGF-I[14] in serum from 16 individual LCMV-infected C3H/St mice yielded a concentration of 0.15 ± 0.02 U ml^{-1} (mean ± 1 s.e.) as compared with mean values from 20 uninfected matched controls of 0.45 ± 0.04 U ml^{-1} (d.f. 34, $P < 0.001$). These results further support a generalized GH deficiency. In the sera, cortisol and insulin levels were normal, but blood glucose decreased markedly (Table 1). The rise in blood sugar after glucose administration in LCMV-infected mice was greater than in uninfected mice (Fig. 2). Histopathological analysis of the pancreas, specifically islets of Langerhans cells, showed normal cell structure and morphology (Fig. 1*H*) by both light and electron microscopy in over 98% of the 500 islets studied. Approximately 2% of islets had cellular infiltrates, but with minimal necrosis. Viral antigen appeared both in accinar cells of the pancreatic ductal tissue and in the β cells of the islets of Langerhans. The amount of insulin in pancreases of LCMV-infected mice ($n = 5$, mean ± 1 s.e.: 0.33 ± 0.02 μU of insulin per g of pancreas) was equivalent to that found in uninfected matched 15-day-old C3H/St controls (0.34 ± 0.04).

To demonstrate definitively the role of GH deficiency in the metabolic disorder of mice infected with LCMV, cloned GH-producing cells (GH-3)[15] were transplanted into 6-day-old nude mice infected at birth with 100 PFU of LCMV. Figure 3 shows that the LCMV-infected recipients of GH grew normally and survived at the rate expected for uninfected age- and sex-matched controls. In contrast, infected littermates without GH transplants died from severe hypoglycaemia associated with their GH deficiency. Mice persistently infected with LCMV and with replaced GH had normal blood glucose levels (infected mice with replaced GH: blood sugar (mg per dl: mean ± 1 s.e.), 128 ± 5, uninfected matched controls 134 ± 8, $P = 0.4$, d.f. $= 14$), and normal glucose tolerance tests (Fig. 4). Hence, the severe disease was caused by GH deficiency associated with LCMV replication in GH-producing cells and was corrected by replacing GH in the virus-infected mice.

There are three primary ways in which viruses could alter cellular function. First, as a result of infection, the cell might release a product like interferon (IFN) that would modulate its function. However, IFN does not have a role in the GH deficiency due to LCMV infection. In our experiments, antibody to mouse IFN that significantly blocked IFN-associated glomerular membrane and liver disease associated with LCMV infection[16–19] (F. J. Dutko and F. Chisari, manuscript in prepar-

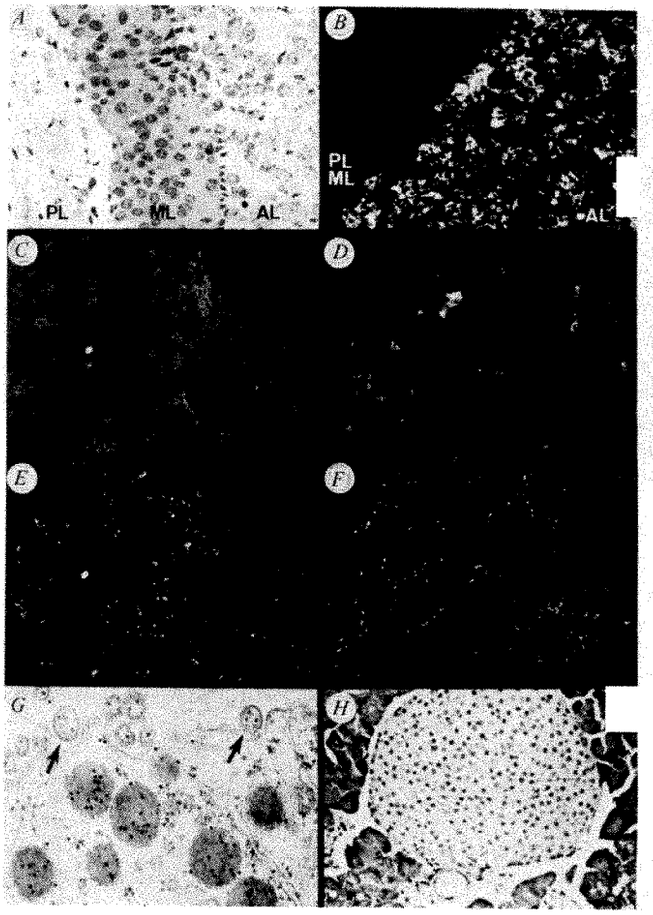

Fig. 1 Histopathological and immunochemical studies of endocrine tissues and cells taken from 15–18-day-old C3H/St mice persistently infected by injection at birth with 60 PFU of LCMV intracerebrally. Intraperitoneal inoculations gave corresponding findings. All mice carried infectious virus as determined by either PFU assay or intracerebral transfer of their sera into 4-week-old susceptible mice. *A*, Normal cell structure and relationships of anterior (AL), middle (ML) and posterior (PL) pituitary lobes. No cell destruction or inflammatory infiltrates are present. *B*, LCMV antigen expression is restricted to cells of the anterior lobe (AL) of the pituitary gland and not to the middle or posterior lobes. Four-micrometre cryostat-cut sections of the pituitary gland were stained with monoclonal antibody to LCMV nucleoprotein and fluorescein isothiocyanate (FITC) dye. Results were similar in over 50 pituitaries from individual LCMV-infected mice examined with these reagents or with a guinea pig polyclonal antibody to LCMV. *C*, *E* represent an identical tissue section. In *C*, tissue is stained with a monospecific antibody to growth hormone (GH) and FITC, while in *E*, tissue is stained with a monoclonal antibody to LCMV nucleoprotein and a rhodamine dye. Results were similar when a monoclonal antibody to mouse GH–FITC was substituted for the monkey antibody to mouse GH. Note similarity of staining pattern indicating that LCMV is replicating in cells making GH. *D*, *F* represent a tissue section stained either with monospecific antibody to prolactin (PL) and FITC or a monoclonal antibody to LCMV nucleoprotein and rhodamine dye (*F*). Note dissimilarity of staining pattern indicating that LCMV is not replicating in PL-containing cells. *G* Demonstrates the replication of LCMV in GH-containing cells of the anterior lobe of the pituitary gland. GH in secretory granules was labelled using monkey antibody to mouse GH and goat antibody to monkey IgG conjugated to gold particles (×17,500). Of over 100 cells studied in the pituitary gland, LCMV (arrows) budded from only those cells with GH-containing vesicles. *H* Illustrates the normal cytomorphology of islet of Langerhans in the pancreas and absence of cell lysis or inflammatory infiltrates. (For methods for plaquing virus, conjugation using two fluorochrome dyes, immunofluorescence, immunoelectron microscopy and light microscopy see refs 7, 8, 10, 25.)

Results from the pituitary gland are in μg pituitary hormone per mg of pituitary gland. Pituitary hormones were isolated, using 10% acrylamide base gel and quantitated by radioimmune assay as described by Sinha[22,23]. Mean values for individual pituitary glands were found. Blood samples from individual mice were assayed. Glucose, sodium and potassium concentrations were determined in 5 to 20 μl of serum using microautomatic Beckman Astra-8. Cortisol and insulin determinations were by radioimmune assay and a competitive inhibition technique. For glucose tolerance tests each mouse received 2 mg glucose per g of body weight, intraperitoneally[24]. Samples obtained from each mouse before glucose challenge and 1 h afterward were tested for glucose and, when sufficient material was left, for insulin and cortisol levels. The numerator represents the number of mice showing a twofold or greater increment in glucose levels 1 h after a measured glucose challenge. The denominator shows the total number of mice studied. Radioimmune assay was used for insulin-like growth factor[20]. NS, not significant; ND, not done.

* Within 18 h of birth, mice were inoculated with 60 PFU of LCMV Armstrong 1371.

† Minimal number of mice per group. ‡ Mean ± 1 s.e.m. § *P* value, NS, not significant difference.

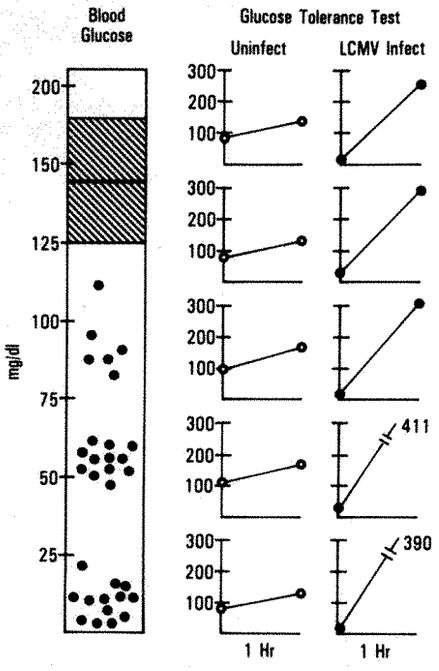

Fig. 2 Perturbation of glucose metabolism in 15-day-old C3H/St mice persistently infected with LCMV. On the left is the mean glucose value of 144 mg dl^{-1} (heavy horizontal line) and 2 s.e. above and below mean (stripped areas) in 48 age- and sex-matched uninfected controls. The blood glucose values for individual C3H/St mice persistently infected with LCMV (●) are shown. On the right are 1-h glucose tolerance tests (GTT) performed on uninfected and LCMV infected mice. Of the 12 uninfected mice studied, none developed twofold increases by 1 or 2 h after receiving 2 mg glucose per g body weight. In contrast, all 10 LCMV-infected mice showed far greater than twofold enhancement in similar conditions. Values for five other LCMV-infected mice not diagrammed were: pre-glucose challenge–post-glucose challenge: 48–570; 60–356; 52–184; 56–334; 52–314.

ation) failed to alleviate deficiencies in either growth or glucose metabolism. Further, IFN levels in the pituitary gland were similar in virus-infected and uninfected matched controls (less than 1.2 units of IFN per g pituitary tissue). Second, the virus might alter cell function by changing the structure of GH. Peptide maps of GH developed by using trypsin or chymotrypsin digests failed to show any structural differences in GH isolated from pituitary glands of infected or uninfected mice (data not shown). Thus, LCMV does not appear to modify the GH polypeptide structurally, although there are no data as yet on the functional activity of these molecules. Third, and most likely, viruses may affect the synthesis of GH at transcriptional or translational levels. Thus, the cells' capacity for membrane translocation and synthesis may be limited so that production of viral gene products competes with manufacture of GH, thereby overloading the system. Alternatively, the virus may induce a specific alteration in an enzyme or transport system needed for the production and release of GH. Work is continuing to investigate these and other possibilities.

Considering the enormous variety of human diseases of which aetiologies are still unknown, it is interesting to speculate that many of these could be caused by failure of the specialized or differentiated function of a cell due to a virus infection. This would include disorders involving faulty manufacture of immune regulators, insulin or other hormones, or neurotransmitters. Others reported[20,21] that viruses can lyse differentiated cells, thereby causing disease. In contrast, we show here that virus causes pathology without cytocidal injury. This may signal a search for viruses in a variety of disorders even in the absence of defined anatomic or morphological changes.

This is Publication No. 3116-IMM from the Scripps Clinic and Research Foundation and was supported by USPHS grants NS-12428, AI-09484 and AG-04342. We thank Drs Yogi Sinha for performing the radioimmune assay of prolactin and Ion Gresser for providing antibody to mouse interferon, Roxanne Fisher, Antoinette Tishon, Paul Blount, Gary McDaniel, Janet Anderson and Robert Garret for technical contributions, and Phyllis Minick and Sally Booz for aid in manuscript preparation.

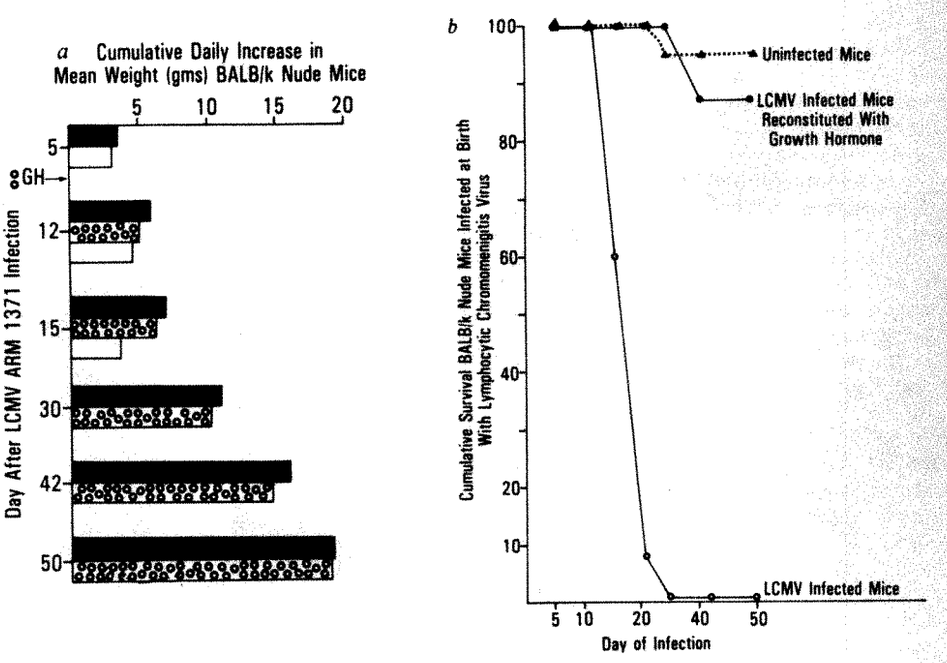

Fig. 3 Transplantation with GH-producing cells corrected the growth deficiency of mice persistently infected with LCMV and allowed a survival rate comparable with that of uninfected age- and sex-matched controls. For these experiments, littermates receiving LCMV at birth were segregated, at random, into three groups. One group received 1×10^7 GH-3 cells (making about 7,800 ng of GH per 24 h in culture) intraperitoneally, initially and twice weekly thereafter. A second group received intraperitoneally, either phosphate-buffered saline or cells not making GH. The third group was not inoculated at all. Each group contained a minimum of eight mice and was handled identically. ■, Uninfected control; □, LCMV-infected but not GH replaced; ⊠, LCMV-infected and GH replaced. Cumulative survival of such 50-day-old uninfected mice and LCMV-infected mice reconstituted with GH exceeded 80%. In contrast, the survival rate of LCMV-infected mice not without replaced GH was <5%.

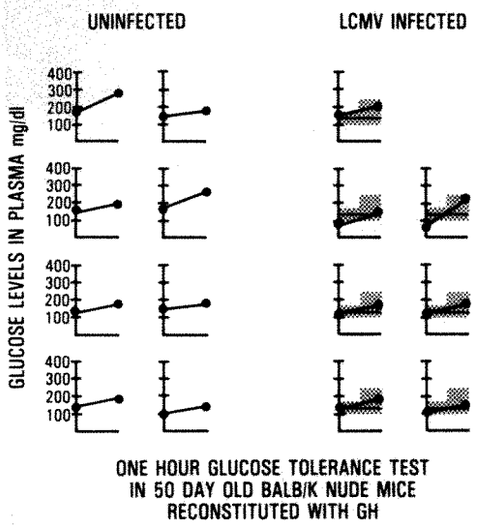

Fig. 4 Replacement with GH normalized the glucose metabolism of mice persistently infected with LCMV. Results of the glucose tolerance test consisted of pre-test samples compared with serum samples taken 1 h after challenge with 2 mg of glucose per g of body weight, intraperitoneally. LCMV-infected mice: horizontal bar represents the mean blood glucose levels of 10 uninfected age matched controls (2 not shown); the shaded area represents 2 s.e.m.

Homologous cell-derived oncogenes in avian carcinoma virus MH2 and murine sarcoma virus 3611

Hans W. Jansen, Rudi Lurz & Klaus Bister*

Max-Planck-Institut für Molekulare Genetik, D-1000 Berlin 33 (Dahlem), FRG

Tom I. Bonner, George E. Mark & Ulf R. Rapp

Laboratory of Viral Carcinogenesis, National Cancer Institute, Frederick, Maryland 21701, USA

Retroviral oncogenes (v-*onc*) are derived from cellular genes (c-*onc*) which are highly conserved among different species[1–3]. Retrovirus-transduced oncogenes are most commonly associated with the induction of haematopoietic tumours and sarcomas[4]. The avian retrovirus Mill Hill no. 2 (MH2) was isolated from a spontaneous ovarian tumour of a chicken and is distinguished by the predominant induction of liver and kidney carcinomas in fowl[4–6]. MH2 also induces transformation of fibroblasts, macrophages and epithelial cells in culture[2,6,7]. The genome of MH2 contains two unrelated and independently expressed cell-derived oncogenes, v-*mil* and v-*myc*[8,9]. Three other viral isolates among avian acute transforming retroviruses

contain the v-*myc* oncogene[2,10], but only MH2 contains both v-*myc* and v-*mil*. Hence, some of the pathogenic specificities of MH2 may be due to the simultaneous expression of two oncogenes. The murine sarcoma virus 3611 (3611-MSV) isolated from a mouse carrying lung carcinoma and peritoneal tumours[11], induces fibrosarcomas in newborn mice and the transformation of fibroblasts and epithelial cells in culture[11,12]. The oncogenic properties of 3611-MSV are due to the presence in its genome of a cell-derived oncogene termed v-*raf*[13]. We report here that the two independently transduced oncogenes v-*mil* and v-*raf* are closely related and that they were apparently derived from homologous cellular genes of avian and mammalian species.

The first indication of a possible sequence relationship between cloned v-*mil* and v-*raf* DNAs came from a comparison of their restriction site patterns (Fig. 1). Both genes have a complexity of ~1.2 kilobases (kb) and share *Sph*I and *Stu*I sites in their central regions. Relative to these sites, the 5′ and 3′ borders of these genes seem to be non-overlapping. Figure 2 provides direct demonstration of sequence homology. Cloned MH2 DNA was digested with appropriate restriction enzymes, and blotted DNA fragments were hybridized to both v-*mil* and v-*raf* probes (Fig. 2*a–c*). All *mil*-containing fragments strongly hybridized with the v-*mil*-specific probe, including fragments resulting from partial digestion and undigested 8.0-kb DNA (Fig. 2*b*). Using the v-*raf*-specific probe, hybridization was observed with basically the same fragments (Fig. 2*c*). The differential intensity of hybridization of specific fragments in the relatively stringent conditions used allowed us to make some conclusions about the regions of strong homology; especially informative was the hybridization of partially and completely digested fragments obtained from digestion with *Stu*I. The 4.60-kb and 3.84-kb fragments of integrated MH2 DNA resulting from incomplete digestion with *Stu*I revealed stronger hybridization to the v-*mil* probe than the fragments of 4.16 and 3.40 kb resulting from complete digestion (Fig. 2*b*), because the larger fragments contain more sequences homologous to the v-*mil* probe. This effect was much more pronounced, however, when the v-*raf* probe was used (Fig. 2*c*), and the 5′ 4.16-kb fragment did not hybridize at all in the conditions used. This implies that the central region of v-*mil*, around the *Sph*I site, contains sequences closely homologous to v-*raf*, while the 5′ and 3′ regions are less homologous, in good agreement with the restriction patterns shown in Fig. 1. Complete confirmation of these conclusions was obtained by digestion of cloned 3611-MSV DNA with appropriate restriction enzymes and hybridization of blotted DNA fragments with both the v-*raf* and v-*mil* probes (Fig. 2*d–f*). Again, fragments containing the central region of v-*raf* around the *Sph*I site, like the 0.50-kb *Hpa*I/*Sst*II fragment, showed the strongest hybridization with the v-*mil* probe (Fig. 2*f*).

Figure 3 shows a heteroduplex analysis between cloned integrated MH2 DNA and a v-*raf*-containing segment of 3611-MSV DNA subcloned in pBR322. Reannealing of denatured DNAs was done in conditions of low stringency and for short periods of time to allow isolation of heteroduplex structures formed between sequences of moderate homology; v-*raf* and v-*mil* sequences annealed over a contiguous segment of ~0.9 kb. The v-*raf*-containing DNA fragment contained about 0.27 kb of pBR322 sequences 5′ from the *Xho*I site of v-*raf* (compare with Fig. 1); since the 5′ single-stranded region (d) of the v-*raf*-containing DNA in the heteroduplex structure was approximately of that length, it seems that homology to v-*mil* starts near the *Xho*I site of v-*raf* and continues for ~0.9 kb. This is in agreement with the alignment of the two genes relative to the conserved *Sph*I site (Fig. 1) and with the pattern of hybridization obtained between cloned v-*mil* and v-*raf* DNAs in Southern blots (Fig. 2).

Chicken and human genetic loci related to v-*mil* and v-*raf*, respectively, have been molecularly cloned and characterized (refs 9, 14 and H.W.J., K.B., T.I.B. and U.R.R., unpublished data). The relationship of v-*mil* and v-*raf* to the chicken and human genes is shown in Fig. 4. DNA of the λ phage clone c-*mil*-4, containing the single-copy chicken locus related to v-*mil*[9], and of a pBR322 clone containing the single active human homologue of v-*raf*, hu c-*raf*-1 [14], were digested with appropriate restriction enzymes. Blotted DNA fragments were hybridized to the v-*mil* and the v-*raf* probe in conditions of high and low stringency (Fig. 4*b–e*). From an *Eco*RI/*Bam*HI digest of c-*mil*-4 DNA, three fragments of 10.0, 2.2 and 1.0 kb hybridized with the v-*mil*-specific probe to a similar extent at high and low stringency, confirming the close homology[9]. In contrast, the v-*raf* probe hybridized only to the 10.0-kb fragment at high and low stringency conditions, and in addition very weakly to the 1.0 kb fragment in low stringency conditions. The 2.2-kb fragment, containing the c-*mil* exon homologous to the extreme 5′ sequences of v-*mil*, did not hybridize at all with v-*raf*, in agreement with the data shown in Figs 1–3. From an *Eco*RI/*Sal*I digest of hu c-*raf*-1 cloned in pBR322, three fragments of 4.8, 3.0 and 0.7 kb hybridized with the v-*raf*-specific probe equally well in high and low stringency conditions, and an additional 2.8-kb fragment hybridized weakly in the relaxed conditions (the 3.7-kb *Eco*RI/*Sal*I fragment of pBR322 hybridized to the pBR322 sequences in the v-*raf* probe). With the v-*mil*-specific probe, the 4.8- and 3.0-kb fragments hybridized in stringent conditions and even stronger in relaxed conditions, and the 0.7-kb fragment hybridized only in low stringency conditions. In general, the data in Fig. 4 confirm the relationship between v-*mil* and v-*raf* demonstrated above, and strongly suggest that these two viral oncogenes were derived from homologous genetic loci. This is also supported by the observation that the same fragments of total digested genomic DNA either of chicken or of human origin hybridized to both the v-*mil* and the v-*raf* probe (not shown). Furthermore, the exon–intron arrangements of the human c-*raf* and the chicken c-*mil* loci seem very similar (refs 9, 14 and T.I.B., U.R.R., H.W.J. and K.B., unpublished data).

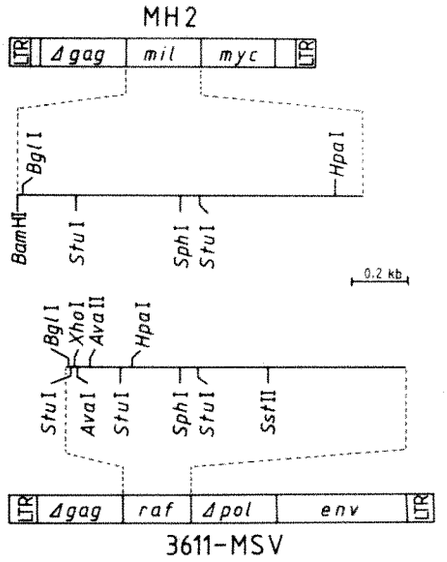

Fig. 1 Comparison of the restriction site patterns of the avian oncogene v-*mil* and the murine oncogene v-*raf*. The location of these genes on the genetic maps of cloned proviral DNAs of MH2 [8,9] and 3611-MSV[13], is shown at the top and bottom, respectively. Both genes are resistant to the following restriction endonucleases: *Bgl*II, *Cla*I, *Eco*RI, *Hin*dIII, *Kpn*I, *Pst*I, *Mlu*I, *Pvu*I, *Pvu*II, *Sst*I, *Sal*I, *Sma*I and *Xba*I.

The extensive sequence homology reported here for the avian oncogene v-*mil* and the murine oncogene v-*raf* strongly supports the view that these two genes were derived from homologous genetic loci of avian and mammalian species. The totally independent transductions of these genes in two highly oncogenic retroviruses of different species directly indicates that the *mil*/*raf* gene family is associated with potential oncogenic

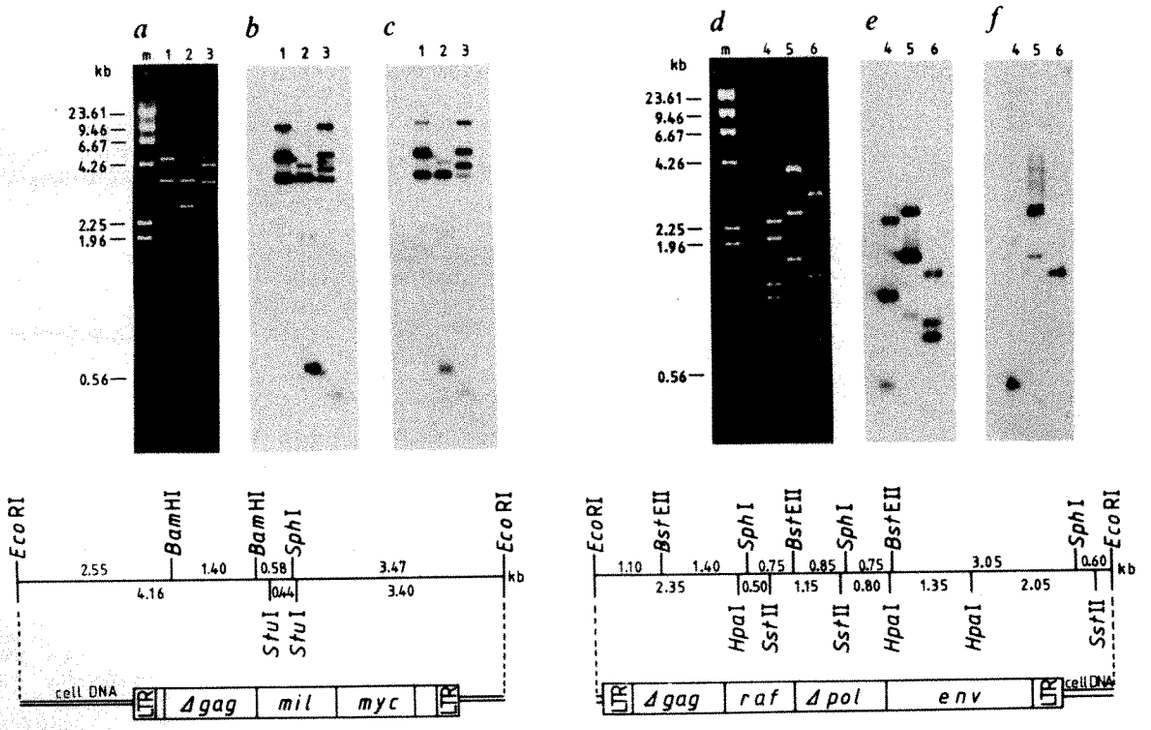

Fig. 2 Detection of sequence homology between v-*mil* and v-*raf*. ***a***, The purified 8.0-kb *Eco*RI fragment of phage clone λ MH2-1 (refs 8, 9), containing the entire MH2 provirus flanked by quail cellular sequences, was digested with *Sph*I (lane 1), *Sph*I and *Bam*HI (lane 2), or *Stu*I (lane 3). The digests were separated in two parallel sets by electrophoresis through a 1.25% agarose gel using a *Hin*dIII digest of λ *c*I857S7 as molecular weight standard (m). Faint bands visible in the ethidium bromide stain result from incomplete digestion of the 8.0-kb fragment. The location and complexities (in kb) of the fragments obtained by these digestions are shown below in the physical map of MH2 DNA. DNA was transferred to nitrocellulose sheets and hybridized with either ***b***, a v-*mil*-specific probe, represented by the gel-purified 1.1-kb *Bam*HI/*Hpa*I fragment of cloned MH2 DNA[8,9] (compare with Fig. 1); or ***c***, a v-*raf*-specific probe, represented by the gel-purified 1.8-kb *Bgl*I fragment of a pBR322 plasmid containing in its *Sal*I and *Hin*dIII sites a 1.9-kb *Xho*I/*Hin*dIII fragment of cloned 3611-MSV DNA extending from the 5′ end of v-*raf* into the Δ*pol* sequences[13] (compare with Fig. 1). The purified 1.8-kb *Bgl*I fragment used as a probe contains 0.27 kb of pBR322, all the v-*raf* sequences 3′ of the *Xho*I site and 0.5 kb of Δ*pol* sequences. Probes were radiolabelled by nick-translation using [α-^{32}P]dCTP to a specific activity of ~5×10^7 c.p.m. μg^{-1}. Hybridization was at 42 °C for 18 h in a solution containing 50% (v/v) formamide, 5×SSC (1×SSC is 150 mM NaCl, 15 mM sodium citrate, *p*H 7.0), 10×Denhardt's solution (0.2% Ficoll, 0.2% bovine serum albumin, 0.2% polyvinylpyrrolidone), 0.1% SDS, 100 $\mu g\ ml^{-1}$ denatured DNA from herring testes, and 1.5×10^7 c.p.m. of the corresponding probes. Filters were washed three times for 45 min each at 65 °C in a solution containing 2×SSC and 0.1% SDS. ***d***, The purified 8.5-kb *Eco*RI fragment of a pBR322 plasmid containing the entire 3611-MSV provirus flanked by mouse cellular sequences[13] was digested with *Hpa*I and *Sst*II (lane 4), *Sph*I (lane 5), or *Sph*I and *Bst*EII (lane 6). The location and complexities of the fragments obtained by these digestions are shown below on the physical map of 3611-MSV DNA. Electrophoresis of the digests, transfer of DNA, and hybridization with: ***e***, the v-*raf* probe; or ***f***, the v-*mil* probe, was as described above.

function. A similar close relationship has been reported between the transforming genes of three different isolates of feline sarcoma viruses and the oncogenes of avian Fujinami sarcoma virus, simian sarcoma virus, or Abelson murine leukaemia virus, respectively[15–17]. Some of these genes belong to a family of oncogenes specifying tyrosine-specific protein kinases[1]. In contrast, no enzymatic activity has been demonstrated yet for the products of the v-*mil* and v-*raf* genes, which are both expressed as *gag*-related hybrid proteins[8,9,11,13]. The oncogenic properties of MH2 and 3611-MSV suggest that the *mil*/*raf* gene family may be involved in epithelial cell transformation. Both viruses transform such cells in culture, and MH2 induces a high

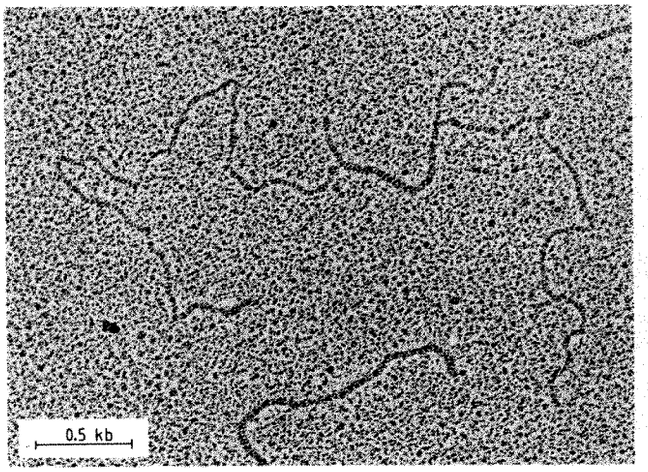

Fig. 3 Homology between v-*mil* and v-*raf* demonstrated by heteroduplex analysis. The purified 8.0-kb *Eco*RI fragment of λ MH2-1 DNA containing the entire MH2 provirus (compare with Fig. 2) and the purified 1.8-kb *Bgl*I fragment containing most of the v-*raf* sequences (see Fig. 2 legend) were used for the analysis, which was done essentially as described previously[9] except that the following parameters were modified: after denaturation of the DNAs, 2 M sodium perchlorate was added to a final concentration of 400 mM and renaturation was for 3 min only. The contour lengths (in kb) of single- and double-stranded regions and their standard deviations were determined: *a*, 4.22±0.31; *b*, 0.92±0.08; *c*, 3.03±0.32; *d*, 0.23±0.04; *e*, 0.59±0.08. From 44 to 53 heteroduplex structures of this type were analysed for the individual length measurements.

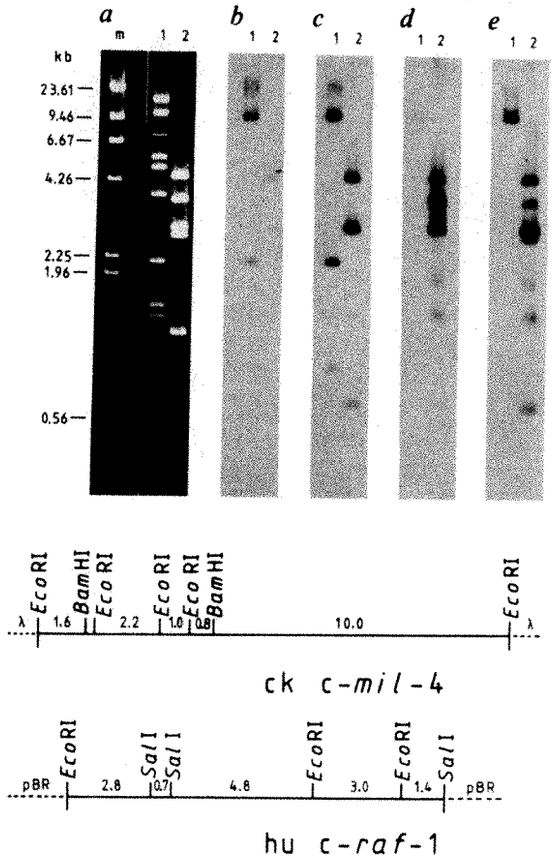

Fig. 4 Sequence relationship of the chicken locus c-*mil* and the human locus c-*raf* to both v-*mil* and v-*raf*. *a*, DNA of λ phage clone ck c-*mil*-4, carrying a 15.9-kb segment of the chicken genome including sequences homologous to all of v-*mil*[9], was digested with *Eco*RI and *Bam*HI (lane 1). DNA of a pBR322 plasmid carrying a 12.7-kb fragment of the human genome including sequences homologous to all of v-*raf* (hu c-*raf*-1)[14] was digested with *Eco*RI and *Sal*I (lane 2). The digests were separated in four parallel sets by electrophoresis through a 1% agarose gel using molecular weight standards (m) as described in Fig. 2 legend. The locations and complexities (in kb) of the fragments obtained are shown on the simple restriction maps of the two cloned loci. DNA was transferred to nitrocellulose sheets and hybridized with the v-*mil* (*b*, *c*) or the v-*raf* (*d*, *e*) probes described in Fig. 2 legend. Hybridization with 2×10^6 c.p.m. of the respective probes was for 4 h in conditions of higher (*b*, *d*) or lower (*c*, *e*) stringency. For higher stringency, conditions were like those described in Fig. 2 legend. For lower stringency, hybridization was at 60 °C in a solution containing 3×SSC, 10×Denhardt's solution, 0.1% SDS and 100 μg ml^{-1} denatured DNA from herring testes. Filters were washed at 60 °C in 2×SSC (*b*, *d*) or 3×SSC (*c*, *e*) containing 0.1% SDS. The autoradiographs were exposed for 30 min using intensifying screens.

incidence of liver and kidney carcinomas *in vivo*. Also, the human homologue of the *mil/raf* gene family is located on chromosome 3 (ref. 14) which is specifically rearranged in small-cell lung carcinoma, certain cases of familial renal carcinoma, and mixed parotid gland tumours[18–22]. We can now analyse whether the human *mil/raf* locus is involved in such specific rearrangements.

We have shown previously that the chicken cellular homologues of the two oncogenes of MH2, c-*mil* and c-*myc*, do not map in close proximity to each other on the chicken genome[9]. We now know that the human c-*mil/raf* gene is located on chromosome 3 (ref. 14), whereas the human c-*myc* gene maps to chromosome 8 (ref. 22). Hence, two unrelated and unlinked cellular genes have been brought together in the MH2 genome. The mechanism of such a dual transduction is unknown, but it is possible that before transduction, the *mil* and *myc* loci had been brought together by chromosomal translocations[22] in the primary tumour from which the virus was isolated. Alternatively, two independent recombinational events between the transducing virus and the cellular genome could have occurred. The presence of two oncogenes on one retroviral genome opens the possibility that these genes may function cooperatively in the induction of specific tumours. Such a synergistic action between oncogenes has been suggested for the cell transformation by another avian retrovirus carrying two oncogenes, avian erythroblastosis virus[23], and for the transformation of primary cell cultures by transfection with pairs of oncogenes belonging to different complementation groups[24,25].

We thank Tilo Patschinsky for useful discussions and Christiane Trachmann for technical assistance.

Cell lineage-specific undermethylation of mouse repetitive DNA

Verne Chapman*, Lesley Forrester*, Janet Sanford*, Nicholas Hastie† & Janet Rossant‡

Several distinct cell lineages are established during mouse embryogenesis. The trophectoderm and primitive endoderm give rise to extraembryonic structures alone, while the primitive ectoderm becomes the fetus proper[1–3]. Recent studies suggest that the levels of DNA modification are lower in inactive X chromosomes from extraembryonic tissues than in embryonic and adult somatic tissues. Using *Hpa*II/*Msp*I isoschizomers, Southern blots and cloned probes, we show here that repetitive DNA sequences from all derivatives of the two extraembryonic lineages, trophectoderm and primitive endoderm, are substantially undermethylated compared with primitive ectoderm derivatives. This contrasts with the highly methylated state of these repetitive elements observed in adult somatic tissues. Specific demethylation or inhibition of *de novo* methylation, or a combination of both mechanisms, may be involved. These findings suggest that elements of gene regulation dependent on DNA modification may be different in extraembryonic cell lineages.

0028–0836/84/030284—03$01.00

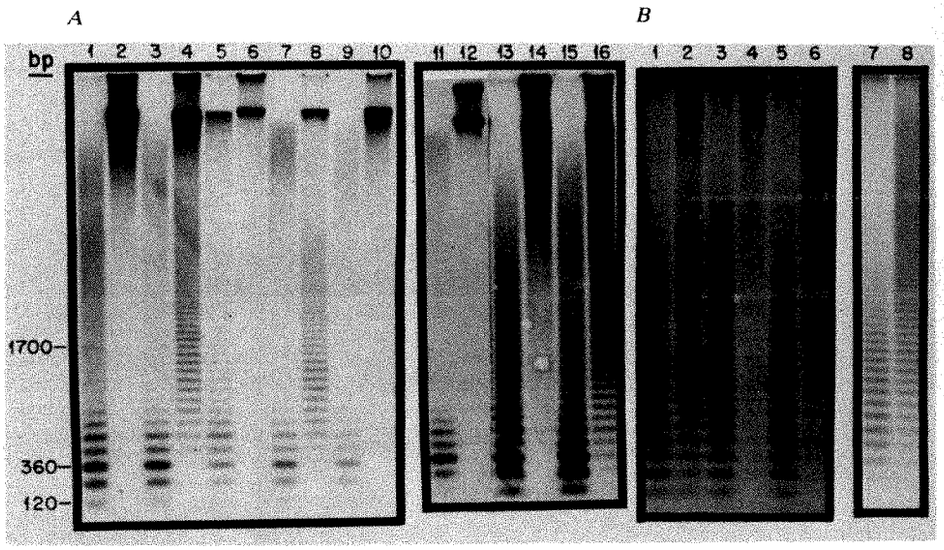

Fig. 1 Southern blot[25] probed with minor satellite sequence (pMR150) for DNA from various sources. Odd-numbered lanes, *Msp*I; even-numbered lanes, *Hpa*II digestion. *A*: lanes 1, 2, liver; 3, 4, sperm; 5, 6, day 7.5 embryonic tissue; 7, 8, day 7.5 ectoplacental cone (epc); 9, 10, day 7.5 decidual cells; 11, 12, day 7.5 embryonic tissue; 13, 14, day 15 yolk sac mesoderm; 15, 16, day 15 yolk sac endoderm. *B*: lanes 1, 2, day 7.5 extraembryonic ectoderm (ex); 3, 4, day 7.5 embryonic tissue; 5, 6, day 7.5 ectoplacental cone (epc); 7, 8, day 12 parietal endoderm. All tissues are from Ha/ICR randomly bred mice. Derivatives of the trophectoderm were obtained from 7.5-day conceptuses, at which stage these tissues can still be isolated free of contaminating ICM-derived tissues. Conceptuses at 7.5 days post-coitum were dissected into embryonic, extraembryonic and ectoplacental cone fractions in phosphate-buffered saline. The extraembryonic regions were further treated with pancreatin (2.5%; Sigma) and trypsin (0.5% in Ca^{2+}, Mg^{2+}-free saline) at 4 °C for 10 min to isolate the extraembryonic ectoderm[26]. Decidual tissue from the day 7.5 conceptuses was also retained for DNA extraction. Derivatives of the primitive endoderm were separated from 12–15-day conceptuses. Parietal endoderm and Reichert's membrane were peeled away from the overlying giant cells[4]. Visceral endoderm was obtained by enzyme separation from the visceral yolk sac[9]. The remaining mesoderm of the yolk sac was also retained. Mature sperm were isolated from cauda epididymides. All tissues were centrifuged, and the saline was replaced by Pronase buffer (50 mM Tris-HCl, *p*H 10, 0.15 M NaCl, 0.1 M EDTA). Liver was Dounce-homogenized in 5% sucrose–TKM (50 mM Tris-HCl, *p*H 7.5, 24 mM KCl, 5 mM $MgCl_2$) buffer, and nuclei were isolated by centrifugation through a 20% sucrose–TKM cushion (5,000 r.p.m., 10 min). The pellet was resuspended in Pronase buffer. Tissue samples were incubated at 37 °C for 30 min in Pronase buffer with 1 mM dithioerythritol (DTE; Sigma). SDS (0.2% final concentration) and preboiled RNase A (150 μg ml^{-1} final concentration; Boehringer Mannheim) were added and cells incubated at 37 °C for 1.5 h. The solution was made up to 0.8% SDS and 150 μg ml^{-1} Pronase (Calbiochem) and incubated for 4 h at 37 °C. The digests were extracted twice with phenol (BRL ultrapure) and three times with chloroform/isoamyl alcohol (24:1). DNA was ethanol-precipitated, desiccated and resuspended in sterile water. DNA yield estimates are 6, 15 and 14 μg from ex, epc and embryo populations respectively for 30 7.5-day conceptuses and 200 μg parietal endoderm DNA from 68 12-day conceptuses. Yolk sac DNA yields are as previously reported[13]. Sperm DNA (800 μg) was extracted from free-swimming sperm released from four minced cauda epididymides. DNA was cut with restriction endonucleases *Msp*I (NE Biolabs) and *Hpa*II (BRL) in conditions recommended by the suppliers. Following overnight incubation, λ DNA was added and incubated for a further 6 h. Restricted DNA (0.5 μg per lane) was subjected to electrophoresis in 0.8% SeaKem Agarose gels using 36 mM Tris, 30 mM NaH_2PO_4, 1 mM EDTA *p*H 7.4 buffer. To confirm complete digestion, we visualized limit-digest λ DNA fragments on the ethidium bromide-stained gel. The DNA was denatured, transferred to nitrocellulose (Schleicher and Schuell 85) and prehybridized in 4×SSC, 5×Denhardt's solution[27], 0.1% SDS, 0.1% Na pyrophosphate and 150 μg ml^{-1} denatured herring sperm DNA for 4 h at 65 °C. ^{32}P (Amersham)-labelled nick-translated[28] pMR150 (specific activity 2×10^8 c.p.m. μg^{-1}, 20×10^6 c.p.m. per blot) was added and hybridized overnight. Filters were washed in 0.5×SSC, 0.1% SDS at 65 °C and radiolabelled bands were visualized after 4 days by autoradiography (XAR-5 Kodak film).

The early stages of mouse embryogenesis are characterized by the establishment of several distinct cell lineages. By 4.5 days of development, two specialized lineages, trophectoderm and primitive endoderm, have been set aside from the pluripotent primitive ectoderm[4], and it is clear that cells are irrevocably committed to separate cell lineages by the late blastocyst stage[5–7]. Studies of X-inactivation suggest that processes controlling gene expression in the specialized trophectoderm and primitive endoderm lineages may differ from those found in pluripotent primitive ectoderm. Derivatives of trophectoderm and primitive endoderm in the developing conceptus share the feature of preferential expression of the maternal X chromosome, whereas primitive ectoderm derivatives undergo random X-inactivation[8–11]. Recent studies using DNA-mediated gene transfer have demonstrated that the DNA of the inactive X chromosome of adult somatic tissues seems to be modified and relatively inefficient in DNA transformation[12]. By contrast, the inactive paternal X chromosome DNA of the visceral yolk sac endoderm (a primitive endoderm derivative) is relatively efficient in transformation and, therefore, is presumed to be less modified[13]. One possible explanation for these findings is that the general levels of DNA modification are lower in extraembryonic tissues than in embryonic and later adult somatic tissues. We have examined the levels of methylation at CpG sites at CCGG tetramers in the DNA of derivatives of different early cell lineages using probes for dispersed and centromeric repetitive DNA families. Comparison of the restriction patterns generated by the restriction endonuclease *Msp*I and the methylcytosine-sensitive isoschizomer, *Hpa*II, reveals that repetitive DNA from all derivatives of the two extraembryonic lineages, trophectoderm and primitive endoderm, was substantially undermethylated compared with primitive ectoderm derivatives and adult somatic tissues.

Several families of repetitive DNA have been identified from a library of cloned mouse (*Mus musculus*) middle repetitive DNA sequences[14]. Two of these cloned probes, pMR150 and pMR134 (pMR = plasmid mouse repetitive), identify families which are characterized by well defined patterns in Southern blots following restriction with *Msp*I. The sequences identified by pMR150 (minor satellite) (Fig. 1) are centromeric and are present in the genome as tandemly repeating elements of 120 base pairs (bp) with $\sim5\times10^4$ copies. By contrast, pMR134 (*Mus* interspersed family, MIF) sequences (Fig. 2) are dispersed throughout the genome with ~30,000 copies of a 5–7-kilobase (kb) element[15–18]. Both of these sequences seem to be fully methylated at CpG sites in adult liver (Fig. 1, lane 2; Fig. 2, lane 2).

The restriction patterns of *Msp*I and *Hpa*II digested DNA from ectoplacental cone (epc) and extraembryonic ectoderm (ex), which are post-implantation derivatives of trophectoderm, are shown for minor satellite sequences in Fig. 1*A*, lanes 7, 8 and *B*, lanes 1, 2. These patterns indicate that a portion of the CpG sites of minor satellites are undermethylated relative to the amount observed in adult liver. By contrast, the DNA from the embryonic portion of the 7.5 day conceptus (Fig. 1, lanes 5, 6, 11, 12) does not seem to be digested by *Hpa*II and produces

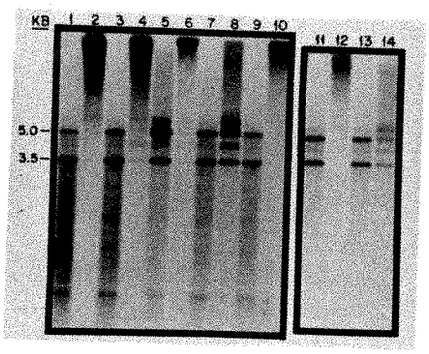

Fig. 2 Southern blot[25] probed with pMR134 (MIF) for DNA from various sources. Odd-numbered lanes, *Msp*I; even-numbered lanes, *Hpa*II digestion. 1, 2, liver; 3, 4, sperm; 5, 6, 7.5-day embryo; 7, 8, ectoplacental cone (epc); 9, 10, decidual cells; 11, 12, yolk sac mesoderm; 13, 14, yolk sac endoderm. All procedures and suppliers were as described in Fig. 1 legend.

a pattern comparable with that observed in adult liver (Fig. 1*A*, lane 2). An unusual *Msp*I pattern of the minor satellite sequences was observed in our original experiments with embryonic DNA (Fig. 1*A*, lane 5). Reanalysis of *Msp*I restriction of embryonic minor satellite sequences suggests that the pattern seen in the first experiment was due to incomplete digestion (Fig. 1*A*, lane 11). This finding suggests that our assessment of the relative *Hpa*II digestion of minor satellite sequences in liver and embryonic DNAs is valid. Maternal decidual cells, which surround the embryo in the uterus, also show extensive methylation of the minor satellite sequences (Fig. 1*A*, lanes 9, 10). *Hpa*II digestion of genomic DNA probed with MIF indicates that the undermethylation observed in epc and ex is not confined to the minor satellite sequences. The level of *Hpa*II digestion of DNA probed with MIF in epc is almost comparable with that produced by *Msp*I (Fig. 2, lanes 7, 8). Embryonic DNA from the 7.5 day conceptus shows no discernible restriction with the methyl-sensitive *Hpa*II (Fig. 2, lanes 5, 6).

We also examined the relative methylation of minor satellite and MIF CpG sites in parietal endoderm from day 12 conceptuses and visceral endoderm dissected from day 15 conceptuses. These two tissues are the later derivatives of the primitive endoderm[4,19]. The Southern blot patterns for minor satellite sequences of *Hpa*II-restricted DNA from these tissues are similar to those observed for epc and ex (Fig. 1*B*, lanes 7, 8 and *A*, lanes 15, 16). The relative digestion of MIF sequences by *Hpa*II also shows significant undermethylation but the levels may be different from those observed in trophectoderm derivatives (Fig. 2, lanes 13, 14). By contrast, the DNA of the yolk sac mesoderm, which is a primitive ectoderm derivative, shows levels of methylation comparable with those seen in embryonic DNA (Fig. 1*A*, lanes 13, 14; Fig. 2, lanes 11, 12). Some *Hpa*II digestion of minor satellite sequences is detectable in the mesodermal extracts (Fig. 1*A*, lane 14). The degree of *Hpa*II digestion is less than that seen in visceral endoderm DNA and could be due to either contamination of mesodermal extracts with endoderm cells during enzyme separation of the two cell layers from yolk sac, or the fact that minor satellite sequences are partially undermethylated compared with embryonic DNA. Previous studies with X-chromosome expression in yolk sac derivatives[9] suggest the first explanation but we cannot rule out the second possibility.

These studies indicate that both centromeric and dispersed repetitive DNA sequences of the mouse are undermethylated in the derivatives of cell lineages differentiated early in embryogenesis, that is, the trophectoderm and the primitive endoderm. By contrast, these same sequences appear to be fully methylated at 7.5 days of development in the primitive ectoderm cell lineage, which gives rise to the embryo. A previous study of methylation levels in total DNA of rabbit embryos also reported undermethylation in trophectoderm[20]. This was attributed to specific demethylation as the trophoblast DNA had the same degree of methylation as adult tissues whereas the embryonic ectoderm DNA was heavily methylated. Whether undermethylation of repetitive sequences in the extraembryonic lineages in the mouse embryo is due to specific demethylation or failure of *de novo* methylation can only be determined unequivocally by examining the levels of methylation in DNA from earlier stages of embryogenesis. However, the levels of methylation of these sequences in oocytes and sperm suggest that both mechanisms may be operating. Both sperm DNA (Fig. 1*A*, lanes 3, 4) and oocyte DNA (J.S., L.F., V.C., A. Chandley and N.H., in preparation) show undermethylation of minor satellite sequences similar to that found in extraembryonic tissues, suggesting that the *de novo* methylase activity known to occur in early embryos[21] may be confined to the pluripotent primitive ectoderm lineage. However, comparison of the levels of methylation of MIF sequences in extraembryonic tissues and sperm suggests that there may also be specific demethylation of some CpG sites in extraembryonic lineages.

The observation that both minor satellite and MIF sequences are undermethylated in certain extraembryonic lineages argues that the undermethylation is not limited to either a particular class of repetitive sequences or a particular chromosomal localization. These data further suggest that the general levels of DNA methylation may be reduced for the entire genome and that elements of gene regulation dependent on DNA modification may differ in these extraembryonic cell lineages. Such differences could conceivably account for the differences in DNA transfer of inactive X-chromosome genes from yolk sac[13] and the undermethylation of human globin genes in placental DNA[22]. It is also conceivable that the presence of some cellular oncogene transcripts in extraembryonic lineages[23] and the expression of endogenous retroviruses in placenta[24] are a function of the undermethylation of DNA in these tissues. Study of the levels of methylation of these and other structural genes in the extraembryonic lineages will determine whether undermethylation is a widespread phenomenon in these tissues. These studies will have considerable implications for the role of DNA modifications in cell lineage development and differentiation.

We thank Dr K. Bennett for the pMR probes and assistance in developing these studies and L. D. Siracusa for helpful discussions and reading the manuscript. This work was supported in part by grants GM24125 from the NIH, USPHS and the Canadian Natural Sciences and Engineering Research Council.

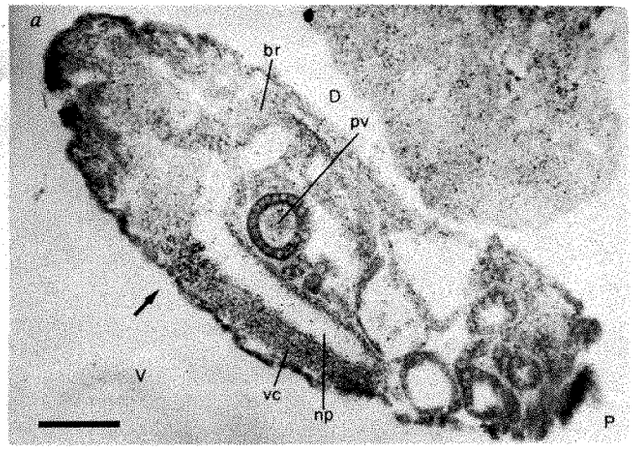
Regulation of *Antennapedia* transcript distribution by the *bithorax* complex in *Drosophila*



Ernst Hafen, Michael Levine & Walter J. Gehring

Department of Cell Biology, Biozentrum, University of Basel, Klingelbergstrasse 70, CH-4056 Basel, Switzerland

The homoeotic genes of *Drosophila* seem to be involved in the establishment of developmental pathways and the specification of different anatomical segment identities[1,2]. For example, it has been proposed that a function of the *Antennapedia*$^+$ (*Antp*$^+$) locus is to direct embryonic cells to follow a mesothoracic developmental pathway[3–5]. Using cloned cDNA probes of the *Antp*$^+$ (ref. 6) locus and an improved *in situ* hybridization method[7], we found that the neural cells of the embryonic and larval mesothorax possess higher levels of *Antp*$^+$ transcripts than the neural tissue of the other segments[7,8]. Here we present further evidence that *Antp*$^+$ products are associated with formation of the mesothorax, obtained by analysing the distribution of *Antp*$^+$ transcripts in *bithorax* mutants. Embryos homozygous for any one of several *bithorax* mutations display a transformation of the epidermis of the more posterior segments into the homologous tissue of the mesothorax[1]. For example, the metathorax and first seven abdominal segments of embryos that completely lack the *bithorax* gene complex show a cuticular phenotype characteristic of the normal mesothorax[1,9]. By *in situ* hybridization of an *Antp*$^+$ cDNA probe to tissue sections of these embryos, we have found that the neural cells of the transformed segments accumulate *Antp*$^+$ transcripts to a level characteristic of the normal mesothorax.

Drosophila neurogenesis involves the formation of a ventral nerve cord. On its initial establishment during early embryogenesis, the ventral cord is a composite of discrete, repeating ganglia[10]. The epidermis of each of the three thoracic and eight abdominal segments of the embryo is innervated by a corresponding ganglion of the ventral cord. Figure 1*a* shows an autoradiograph of a tissue section through an 18-h wild-type embryo after hybridization to a tritium-labelled *Antp*$^+$ cDNA probe. The same tissue section is shown in Fig. 1*b* after dark-field photomicroscopy. At this advanced stage of embryogenesis, condensation of the ventral nerve cord has resulted in the loss of overt segmentation. Nonetheless, from similar examination of younger embryos[7,8], it is clear that the highest accumulation of silver grains corresponds to the ganglion cells of the mesothoracic segment (arrow). It is possible that the strong hybridization signal includes some of the ganglion cells in the posterior portion of the prothoracic segment. Comparisons of tissue sections through different embryos of the same stage indicate that the orientation of these strongly labelled cells is roughly constant with respect to the proventriculus (pv), which therefore serves as an indicator of the mesothoracic ganglion. The other ganglia of the ventral cord display much weaker labelling.

The chromosomal deficiency *Df(3R)P9* deletes all known genes of the *bithorax* complex and embryos homozygous for this allele die during the terminal stages of embryogenesis. Inspection of the cuticle of such embryos indicates that the metathorax and the first seven abdominal segments acquire features characteristic of both the posterior portion of the normal prothoracic segment and the anterior portion of the mesothorax[1,4,9]. Figure 2*a* shows an autoradiograph of an embryo homozygous for the *P9* deficiency after hybridization to the *Antp*$^+$ cDNA probe. The corresponding dark-field photomicrograph of this tissue section is shown in Fig. 2*b*. As compared with a wild-type embryo of similar age (Fig. 1), a much larger proportion of the ventral ganglion cells is strongly labelled in the *P9* embryo. This labelling extends uniformly posteriorly from the ganglion cells of the mesothoracic segment through those of the first seven abdominal segments. As in wild-type embryos, the ventral ganglion cells of the anterior portion of the prothoracic segment and of the 8th abdominal segment show considerably less labelling at this stage.

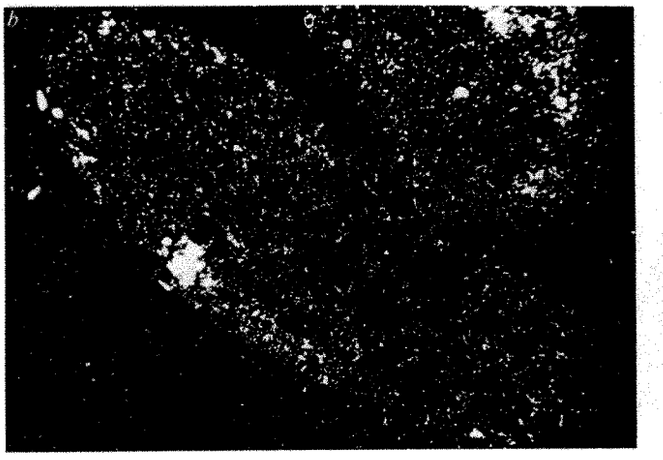


Fig. 1 Localization of *Antennapedia*$^+$ (*Antp*$^+$) transcripts in a sagittal section through an 18-h wild-type embryo. *a*, A bright-field photomicrograph of the embryo section; *b*, a dark-field photomicrograph of the same embryo section. The diagram in *a* is a schematic representation of the segmentation pattern of the embryonic cuticle and the nervous system. A, anterior aspect of the embryos; A1–A8, eight abdominal ganglia of the ventral nervous system; br, brain; D, dorsal aspect of the embryo; np, neuropile; P, posterior aspect of the embryo; pv, proventriculus; T1–T3, three thoracic ganglia of the ventral nervous system; V, ventral aspect of the embryo; vc, ventral cord. Scale bar, 0.1 mm. The section was hybridized to the 903 *Antp*$^+$ cDNA probe and autoradiographed for 15 days. 903 is a pBR322 recombinant containing a 2.2-kilobase (kb) cDNA insert that is the reverse transcription product of poly(A)$^+$ RNA extracted from 0–8 h wild-type embryos. This cDNA segment was shown to share homology with four non-contiguous chromosomal DNA sequences encompassing 100-kb cloned genomic DNA derived from the *Antp*$^+$ locus[6]. The 903 recombinant was tritium-labelled and hybridized to frozen tissue sections of staged wild-type embryos as previously described[7]. The arrow indicates strong hybridization of the 903 cDNA probe to the mesothoracic ganglion cells.

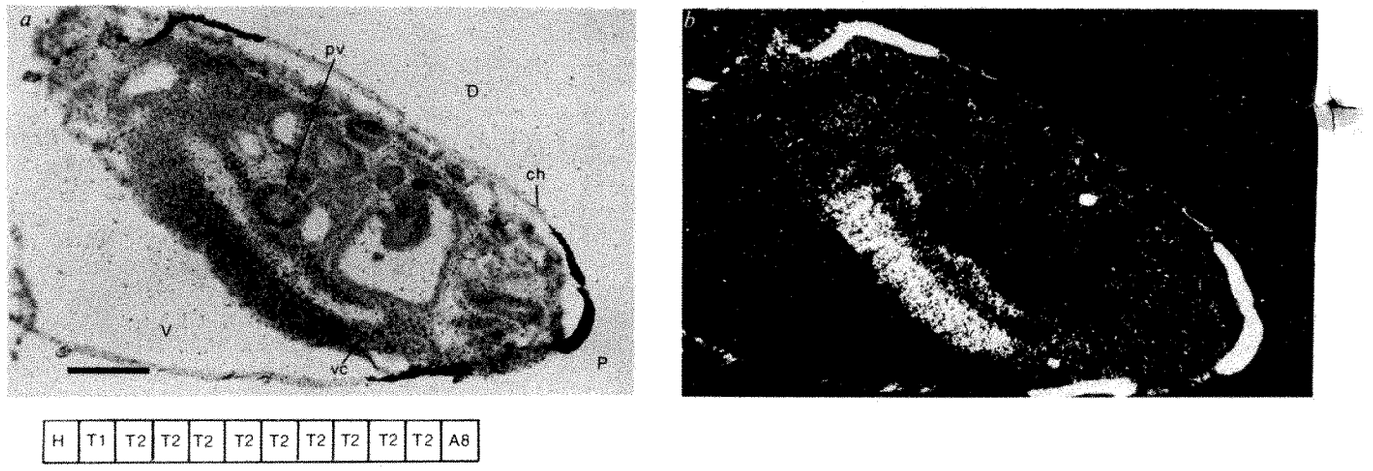

Fig. 2 Localization of *Antennapedia*$^+$ (*Antp*$^+$) transcripts in an embryo homozygous for the *P9* deficiency of the *bithorax* complex. A dark-field photomicrograph of the section shown in *a* is presented in *b*. The diagram in *a* is a schematic representation of the cuticular segmentation pattern of the embryos homozygous for the *P9* deficiency. Abbreviations as in Fig. 1 and ch, chorion shell. Scale bar, 0.1 mm. Embryos were collected from the mutant strain *Dp(3.3)P100/Df(3R)P9* (kindly provided by E. B. Lewis) for 4 h and the embryos were allowed to develop at 25 °C for an additional 26 h, so that all the viable embryos were able to hatch. The unhatched embryos were collected and sections were prepared as described previously[7] except that the embryos were embedded without removal of the chorion shell and without prefixation in paraformaldehyde. *a* Shows a sagittal section through a 26-h embryo homozygous for the *P9* deficiency after hybridization to the 903 *Antp*$^+$ cDNA probe and autoradiography for 24 days.

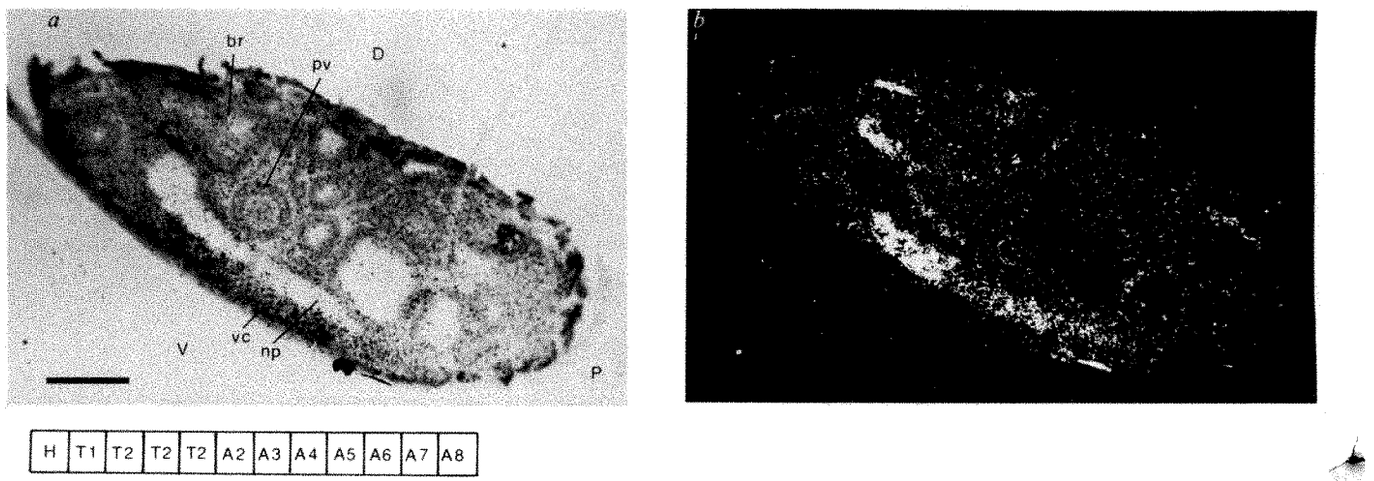

Fig. 3 Localization of *Antennapedia*$^+$ (*Antp*$^+$) transcripts in a homozygous *Ubx*^{105} embryo. Embryos were collected from four winged flies heterozygous for *Ubx*^{105} and two recessive *bithorax* alleles, *bx* and *pbx*. *a*, A sagittal section through a 20-h embryo homozygous for *Ubx*^{105} after hybridization to the 903 *Antp*$^+$ cDNA probe and autoradiography for 24 days; the diagram is a schematic representation of the cuticular segmentation pattern of embryos homozygous for *Ubx*^{105}. The accumulation of silver grains at the presumptive mouthhooks does not appear to be due to specific interaction of the probe DNA with a cognate RNA, since the same pattern was occasionally observed with control hybridization probes not derived from the *Antp*$^+$ locus. *b*, Dark-field photomicrograph of the same section as in *a*. Abbreviations as in Fig. 1. Scale bar, 0.1 mm.

In addition to the homoeotic transformation of the metathoracic and abdominal epidermis in *P9* embryos, it has been shown that the ganglia of these more posterior segments possess some of the morphological features characteristic of a normal thoracic ganglion[11]. During the latter periods of normal embryogenesis the ganglion cells of the mesothorax possess substantially higher concentrations of *Antp*$^+$ RNAs than do the ganglion cells of the other segments[7,8]. Therefore, strong hybridization signals with the *Antp*$^+$ cDNA probe serve to indicate the identity of mesothoracic ganglion cells. As a result, the strong labelling of the metathoracic and first seven abdominal ganglia of *P9* embryos is a further indication that, in addition to the epidermis, there is also a corresponding mesothoracic transformation of the neural tissue.

The distribution of *Antp*$^+$ transcripts was also examined in embryos homozygous for the *Ubx*^{105} allele of the *bithorax* gene complex. Such individuals die either during late larval development or during pupation. The terminal cuticular phenotype of *Ubx*^{105} homozygotes involves the transformation of the metathorax and first abdominal segment into a mesothorax (ref. 1 and E. B. Lewis, personal communication). Figure 3*a* shows an autoradiograph of a 20-h embryo homozygous for *Ubx*^{105} after hybridization to the *Antp*$^+$ cDNA probe. The corresponding dark-field photomicrograph is shown in Fig. 3*b*. As compared with the wild-type pattern shown in Fig. 1, a larger proportion of ventral ganglion cells display strong hybridization signals. The anterior-most labelled ganglion cells are located in a similar position with respect to the proventriculus as are the mesothoracic ganglion cells of a wild-type embryo of similar age (Fig. 1). However, in contrast to the wild-type hybridization pattern, an increased accumulation of silver grains is also observed in more posterior ganglion cells. Based on estimates of the number of ganglion cells within each segment of the ventral cord, the extent of the labelling is sufficient to encompass the metathoracic and first abdominal ganglia. Thus, in the absence of normal *Ubx*^{105} function, there appears to be a trans-

formation of both the neural and epidermal tissue of the metathorax and first abdominal segment to the homologous tissue of the mesothorax.

The results presented here indicate that *bithorax* mutants which are wild type with respect to the $Antp^+$ gene exhibit an altered pattern of $Antp^+$ expression. In such individuals a close correlation has been established between the phenotypic transformation of the cuticular portion of the metathoracic and abdominal segments to a mesothorax and an augmented steady-state level of $Antp^+$ RNA present in the ganglion cells of the affected segments. Evidence supporting a role for $Antp^+$ products in the specification of the mesothorax had been previously obtained by examination of the pattern of $Antp^+$ expression in wild-type embryos by *in situ* hybridization[7,8]. Even during early periods of normal embryonic development the mesothoracic segment in the ventral nervous system is associated with relatively high levels of $Antp^+$ RNAs[8]. The present study substantially extends this observation. In the absence of normal *bithorax* function, $Antp^+$ RNAs accumulate in the progenitors of more posterior ventral ganglia where they might function to impose a mesothoracic developmental pathway.

During early periods of normal embryonic development, $Antp^+$ transcripts are detected in the neural progenitors of each of the thoracic and abdominal ganglia. However, during subsequent development, the RNAs that are initially detected in the pro-, metathoracic and abdominal ganglia gradually diminish such that by mid-embryogenesis the mesothoracic ganglion cells contain the highest concentrations of $Antp^+$ transcripts[8]. Once established, this segment-specific pattern of $Antp^+$ expression is maintained through the remaining periods of embryonic development and subsequent larval development. It has been proposed that expression of the *bithorax* gene complex is confined to the metathoracic and abdominal segments[1]. Consistent with this proposal is the recent demonstration that *Ultrabithorax*$^+$ (Ubx^+) transcripts are distributed along the ventral cord of developing wild-type embryos as observed for $Antp^+$ transcripts, except that by late embryogenesis the ganglion cells of parts of the metathorax and the first abdominal segment possess the highest concentrations of Ubx^+ RNAs[12]. $Antp^+$ transcripts might be prevented from reaching high steady-state levels in the posterior ganglia of wild-type embryos by the *bithorax* products which are also present in these cells. In the mesothorax, $Antp^+$ RNAs stably accumulate since *bithorax* products are largely absent from this segment. Thus, one possible explanation for the increased levels of $Antp^+$ transcripts in the metathoracic and abdominal ganglia of *P9* embryos is the absence of *bithorax* products from these positions. This interpretation of the results agrees with previous genetic findings which suggest a direct or indirect regulatory influence of products from the *bithorax* complex on the proper expression of genes in the *Antp* complex[5].

We thank Bill McGinnis for discussing and reviewing the manuscript and Erika Wenger-Marquardt for assistance in preparing the manuscript. Activation of extra copies of genes coding for nitrogenase in *Rhodopseudomonas capsulata*

Pablo A. Scolnik & Robert Haselkorn

Department of Biophysics and Theoretical Biology, The University of Chicago, Chicago, Illinois 60637, USA

Biological nitrogen fixation requires the nitrogenase enzyme complex, ATP, and a strong reductant[1]. *Klebsiella pneumoniae* contains 15 linked nitrogen fixation (*nif*) genes[2,3], three of which, *nifH*, *nifD* and *nifK* have been sufficiently conserved in evolution that cloned *K. pneumoniae nifHDK* DNA[4] will hybridize to DNA sequences from every nitrogen-fixing bacterium examined to date, including the purple, non-sulphur bacterium *Rhodopseudomonas capsulata*[5], in which one complete *nifHDK* operon has been mapped[6]. Using cloned *K. pneumoniae nifHDK* DNA we report here that *R. capsulata* contains multiple copies of the genes for nitrogenase components. Two regions containing sequences homologous to all three *nif* structural genes have been identified, and mutations in one region produced a Nif$^-$ phenotype. Nif$^+$ pseudorevertants were derived from these mutants, some of which retained the original mutation suggesting that some of the extra *nif* gene sequences can be functionally activated.

Hybridization of pSA30 to a *Hin*dIII digest of total DNA from *R. capsulata* shows two strong bands of 11.8 kilobasepairs (kbp) and 4.9 kbp, as well as additional bands of lower intensity (and presumably lower homology) (Fig. 1, lane *a*). A *nifH* gene-specific probe hybridized only to the 11.8 and 4.9-kbp fragments (lane *b*), while *nifD* and *nifK* probes annealed to several additional bands including two at 3.6 and 1.9 kbp (lanes *c*, *d*). The 11.8-kbp *Hin*dIII fragment contains the functional *nifHDK* operon previously mapped[6], referred to as 'copy I' (Fig. 3, for strain SB1003). The results in Fig. 1 show that there is at least one additional *nifH*-related sequence in the 4.9-kbp *Hin*dIII fragment and several additional *nifD*- and *nifK*-related sequences. Other related sequences appear to be present on two larger fragments as well.

Multiple copies of *nif* gene-related sequences are also seen in the *Eco*RI digest, particularly with the single gene probes. The two bands that are identified by pSA30 at 7.6 and 5.0 kbp (lane *e*) derive from copy I; an *Eco*RI site is near the C-terminal end of the *nifD* gene (Fig. 3). Three additional bands, 11.0, 6.5 and 6.0 kbp, are identified by all three single gene probes (lanes *f*–*h*), enabling us to conclude that *R. capsulata* contains at least four copies of sequences related to the structural genes for nitrogenase components.

To clone the *nif*-related sequences for detailed study, we first isolated a fragment of copy I DNA by screening a library of recombinant λ containing *Eco*RI fragments of *R. capsulata* DNA in λgt7-*ara*6 (R. W. Davis, unpublished). One such recombinant phage contained the 7.6-kbp *Eco*RI fragment from copy I, which contains all of *nifH* and most of *nifD* (Fig. 1, lanes *e*–*h*, and Fig. 3). That fragment was purified and used to probe a cosmid library of *Hin*dIII fragments (Fig. 1 legend). Two cosmids were found to contain related sequences. Plasmid p103 contains the 11.8-kbp *Hin*dIII fragment and an additional 32 kbp of adjacent chromosomal DNA, while plasmid p108 contains the 4.9-kbp *Hin*dIII fragment and an additional 40 kbp of chromosomal DNA. The two cosmids have no restriction fragments in common.

Further study of the relationships among the *nif*-related sequences was facilitated by subcloning the 11.8- and 4.9-kbp *Hin*dIII fragments from p103 and p108, respectively, into the mobilizable vector pRK292 (ref. 7). The results of hybridizing each of these plasmids back to total chromosomal DNA of *R. capsulata* are shown in Fig. 1, lanes *j* and *l*. These results indicate that the extra copies are more closely related to each other than any of them is to copy I.

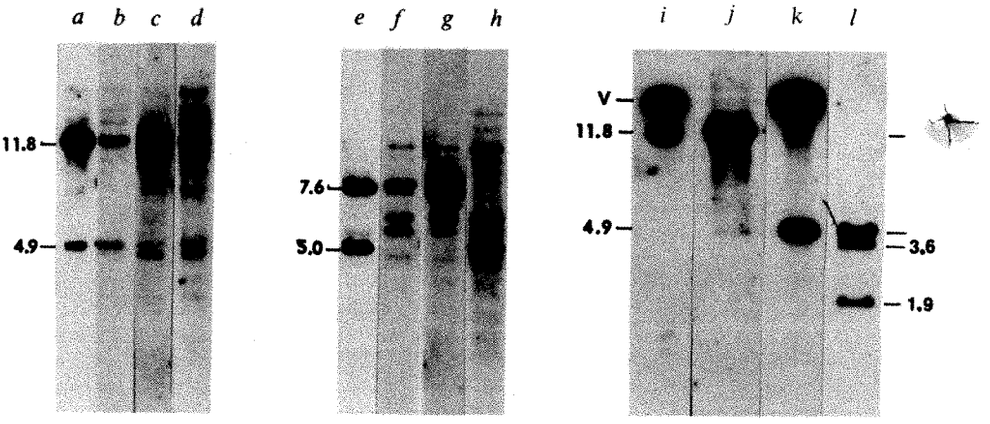

Fig. 1 Multiple copies of *nif* gene-related sequences in *R. capsulata* DNA revealed by Southern hybridization with heterologous probes. Lanes *a–d* contained *R. capsulata* DNA digested with *Hin*dIII; lanes *e–h* the same DNA digested with *Eco*RI. Radioactive probes contained *Klebsiella nifHDK* DNA (lanes *a, e*), *Klebsiella nifH* (lanes *b, f*), *Anabaena nifD* (lanes *c, g*) and *Klebsiella nifK* (lanes *d, h*). The 11.8-kbp *Hin*dIII fragment and two major *Eco*RI fragments of 7.6 and 5.0 kbp are derived from copy I of the *nifHDK* operon (see map in Fig. 3). The 11.8-kbp and 4.9-kbp *Hin*dIII fragments were isolated from a cosmid library and subcloned in pRK292 to yield plasmids pRPA5 and pRPA7, respectively. pRPA5 was used as probe in Southern hybridization to *Hin*dIII cut pRPA5 (lane *i*) or total *R. capsulata* DNA (lane *j*). pRPA7 was the probe with pRPA7 (lane *k*) or total *R. capsulata* (lane *l*). V indicates the vector DNA band. The extra copy probe, pRPA7, identifies copies which were less visible in lanes *c* and *d*.

Methods: Total DNA from *R. capsulata* was isolated by the method of Bendich *et al.*[18]. Approximately 2 μg were digested with *Hin*dIII or *Eco*RI and the resulting fragments were separated on 0.7% agarose gels. DNA was transferred to nitrocellulose by the method of Southern[19] and annealed with $1–2\times10^6$ d.p.m. of ^{32}P-labelled nick-translated probe. Hybridization was for 20 h at 65 °C in 5×SSPE, (0.15 M NaCl, 0.01 M NaH_2PO_4, 1 mM Na_2EDTA, *p*H 7.0) followed by three 45-min washes in 3×SSPE. The *Klebsiella nifHDK* probe pSA30 has been described[4]. The internal *nifH* probe was prepared by subcloning an *Eco*RI–*Bgl*II fragment[4] from pSA30 into pBR322 cut with *Eco*RI and *Bam*HI. The *nifD* probe was pAn256, which contains most of the *nifD* gene of *Anabaena* 7120[15]. The internal *nifK* probe was prepared by subcloning a *Sal*I fragment[4] from pSA30 into the *Sal*I site of pBR322. The cosmid library of *R. capsulata* DNA was prepared from a size-fractionated *Hin*dIII partial digest ligated into the cosmid vector pDPT5Cm (ref. 20) and maintained in *E. coli* HB101. Screening the library with the 7.6-kbp *Eco*RI fragment (lane *e*), which had been isolated from a λ phage library, yielded cosmids p103 and p108. Each cosmid contained over 40 kbp *R. capsulata* DNA. The 11.8-kbp *Hin*dIII fragment (copy I) was subcloned from p103 into the mobilizable plasmid pRK292 (ref. 7) to yield pRPA5 (lanes *i, j*). The 4.9-kbp fragment was subcloned from p108 into pRK292 to yield pRPA7 (lanes *k, l*).

We next wished to study the functional properties of the cloned *nif* gene-containing fragments. For this purpose, we designed a method for site-specific mutagenesis of *R. capsulata* using the gene transfer agent (GTA)[8], a defective transducing phage that packages 4.6-kbp of linear, double-stranded chromosomal DNA fragments[9], to make insertions or deletions. The method is illustrated in Fig. 2. Briefly, a 2.4-kbp *Xho*I fragment (the 'cartridge'), carrying the gene for kanamycin resistance from Tn*5* (ref. 10) (which is expressed in *R. capsulata*) is ligated *in vitro* into a *Xho*I, *Sal*I or *Ava*I site in a cloned target fragment. The plasmid so constructed is used to transform *Escherichia coli* and then mobilized into a GTA-overproducing strain of *R. capsulata*. Finally, GTA from this strain is used to transfer Km^r to a recipient *R. capsulata*. Km^r transductants are produced by a double recombination event, one in each of the sequences flanking the Km^r gene. Although this method can only be used in *R. capsulata*, it has the advantages over previously described procedures[11] that it does not depend on transposition to generate insertions and it does not leave a plasmid behind after the insertion or deletion is created in the recipient chromosome.

The results of hybridization to *Hin*dIII digests of total DNA from wild-type *R. capsulata* and from strain 1051, in which the Km^r cartridge has been inserted in the *Sal*I site of the *nifH* gene of copy I, are shown in Fig. 2, *e* and *f*, respectively. The probe in this case was pRPA5, which contains the cloned 11.8-kbp fragment. The 2.4-kbp Km^r cartridge contains a single *Hin*dIII site (Fig. 2), so inserting it into the *nifH* gene introduces a new *Hin*dIII site into the 11.8-kbp fragment. The two fragments produced, 9.9 and 4.3 kbp, correspond to the sum of 11.8 and 2.4 kbp.

Maps of one insertion and two deletions produced in copy I by this method are shown in Fig. 3, with details of the strain constructions. Southern hybridizations confirming the map positions of the insertions and deletions are shown in Fig. 4. The hybridization of DNA from strain 1051 was described above. In strain DN51, the 750-bp *Xho*I fragment in *nifD* was deleted and replaced with the 2.4-kbp Km^r cartridge. Thus, the 11.8-kbp *Hin*dIII fragment is replaced by two new fragments (Fig. 4, lane *d*) that total 13.4 kbp, while the 7.6-kbp *Eco*RI fragment is replaced by one of $7.6+2.4-0.75=9.25$ kbp (Fig. 4, lane *h*). The latter result can be compared with that for strain 1051 (lane *f*) in which the insertion was made without deletion; the new band in that case is 10.0 kbp. Finally, in strain 306, the large *Ava*I fragment entirely within the 7.6-kbp *Eco*RI fragment was deleted and replaced with the Km^r cartridge. In Fig. 4, lane *c*, the two new *Hin*dIII fragments total 7.2-kbp and in lane *g* the new *Eco*RI fragment is 3.0 kbp, consistent with the map shown in Fig. 3. The blots in Figs 2 and 4 also show that only the target sequence is affected; the extra copies are unaltered in strains in which the Km^r marker was inserted in copy I. All of the strains in which the Km^r marker was inserted in copy I are Nif$^-$, indicating that, in the conditions used in the laboratory, only copy I *nifHDK* genes are functional. This conclusion has also been reached on the basis of complementation of independently isolated Nif$^-$ point mutants by the cloned copy I fragment[6].

The insertions and deletions created in copy I *nif* genes should not revert. However, Nif$^+$ pseudorevertants were obtained from both types of mutations. We obtained Km^r, Nif$^+$ strains from each of the mutants shown in Fig. 3. Such strains grew slowly in nitrogen-free media and had about 10% of the wild-type acetylene reduction activity. These strains retained the Km^r cartridge in the copy I genes, shown by hybridization to total DNA prepared from the revertants (data not shown). Some Nif$^+$ revertants of strain 1051 were found to be Km^s. These strains had wild-type level nitrogenase activity and their DNA showed restoration of the wild-type restriction pattern (*Hin*dIII and *Eco*RI) in the copy I genes. We think that, in these strains, extra copy *nifH* sequences were used to convert (delete) the inserted cartridge at copy I. Precise excision of the cartridge is less likely because the only region of homology at the ends of the insert is the *Xho*I site.

These results indicate that sequences homologous to all three structural genes for nitrogenase are present in several copies in the *R. capsulata* genome, but differences in the restriction pattern and in the intensity of hybridization with the specific probes indicate that the multiple sequences are not identical. Do the extra copies of the *nif* genes have any physiological meaning? At present we know too little about them to offer an

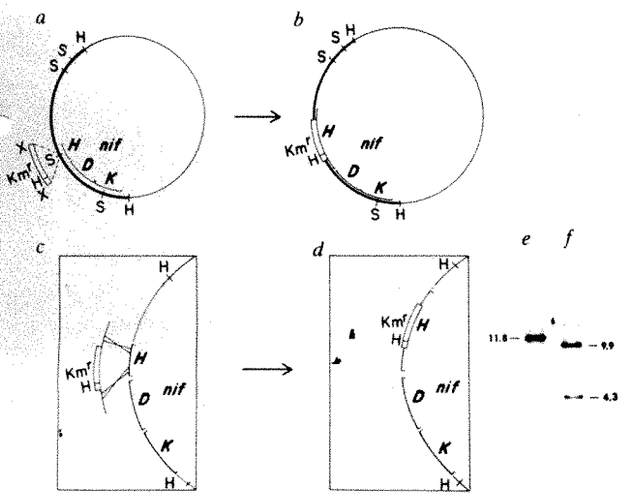

Fig. 2 Site-directed mutagenesis of *Rhodopseudomonas capsulata* with a kanamycin resistance gene cartridge. ***a***, Plasmid pRPA5 DNA (Tet^r) was digested with *Sal*I in the presence of ethidium bromide[21] to generate one cut per molecule. A 2.4-kbp *Xho*I fragment carrying Km^r from Tn*5* was ligated in and the resulting plasmid population was used to transform *E. coli* HB101, selecting for tetracycline and kanamycin resistance, to yield *b*. Plasmid DNA from individual clones was extracted and digested with *Hin*dIII and *Eco*RI. The Km^r cartridge contains one *Hin*dIII site and no *Eco*RI sites, so the original 11.8-kbp fragment is replaced in the insertions by two *Hin*dIII segments (9.9 and 4.3 kbp for the insert in *nifH* oriented as shown), and the 7.6-kbp *Eco*RI fragment containing *nifH* and most of *nifD* (see map in Fig. 3) is replaced by a 10-kbp fragment. Insertions in several *Sal*I sites were obtained. The insert in the *nifH* site was identified by hybridizing the *Hin*dIII cut plasmid fragments with ^{32}P-labelled pSA30. Since this probe is homologous only to the *nifHDK* region and both *Hin*dIII fragments showed homology, the insertion has to be in the *nifH Sal*I site shown. ***b***, This plasmid was then mobilized into *R. capsulata* Y262, a gene transfer agent (GTA) overproducer[9], using the helper plasmid pRK2013. The conjugational cross was done on RCVB minimal medium, selecting for tetracycline resistance (5 μg ml^{-1}). *E. coli* HB101 does not grow in this medium. GTA was prepared from these cells[9] and used to transduce wild-type *R. capsulata* SB1003, selecting for Km^r. Since GTA transduces linear, double-stranded segments of DNA 4.6 kbp in size, any fragment containing genomic DNA on both sides of the Km^r cartridge can recombine with the target sequences in the chromosome of the recipient cell (**c**) generating a Km^r mutant (strain 1051) (**d**). Total genomic DNA from strains SB1003 (**e**) and 1051 (**f**) was digested with *Hin*dIII, and the fragments separated in a 0.7% agarose gel, blotted onto nitrocellulose and hybridized with ^{32}P-labelled pRPA5 DNA. The *Hin*dIII site is 750 bp from one end of the *Xho*I Km^r fragment. The *Sal*I site is 3.55 kbp from the right end of the 11.8-kbp *Hin*dIII fragment of wild-type DNA. Thus, the wild-type 11.8-kbp band in **e** has been replaced by two fragments (9.9 and 4.3 kbp) in strain 1051 (**f**), corresponding to 8.25+1.65 kbp and 0.75+3.55 kbp, respectively. This method may also be used to generate deletions (Figs 3, 4) by removing a restriction fragment at the time of cartridge insertion *in vitro*.

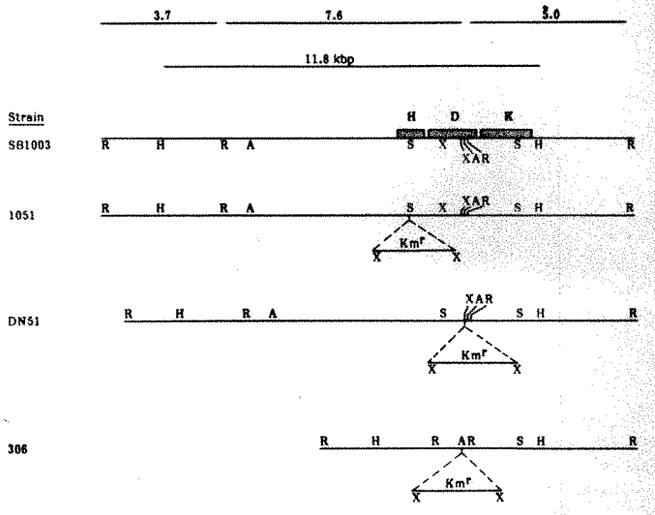

Fig. 3 Physical map of the copy I *nifHDK* region in different strains of *R. capsulata*. Lines at the top of the figure indicate the *Eco*RI and *Hin*dIII fragments, labelled in kbp, in wild-type *R. capsulata*, that hybridize with pRPA5. The *Eco*RI 7.6-kbp fragment contains the *nifH* gene and most of the *nifD* gene (see Fig. 1 and ref. 6). The 5.0-kbp *Eco*RI fragment contains the *nifK* gene. Location of genes and sites for *Eco*RI(R), *Hin*dIII(H), *Sal*I(S), *Ava*I(A) and *Xho*I(X) are shown for the wild-type strain (SB1003). Strain 1051 carries a Km^r cartridge insertion in the *nifH Sal*I site. DN51 has a 750-bp deletion of the *Xho*I segment in *nifD*. Strain 306 has a 7.0-kbp deletion between *Ava*I sites within the 7.6-kbp *Eco*RI fragment. The *Hin*dIII site in the Km^r cartridge is not shown in this figure.
Methods: Construction of strain 1051 was explained in Fig. 2 legend. To construct strain DN51, the *Sal*I fragment of SB1003 containing sequences from *nifH* to *nifK* was subcloned into pBR322, and then digested with *Xho*I (which does not cut pBR322). To the resulting DNA we ligated the Km^r cartridge, and then transformed *E. coli* HB101, selecting for Tet^r Km^r. The resulting plasmid was mobilized by conjugation into *R. capsulata* Y262 with the helper plasmid pDPT51, selecting for Km^r. GTA was prepared and used to transduce Km^r to SB1003. Substitution of the target sequence by the segment carrying the Km^r cartridge results in the insertion of the cartridge and consequent deletion of the *Xho*I segment. To construct strain 306, we carried out a partial digestion of plasmid pRPA5 with *Ava*I. After inactivation of the enzyme, this DNA was ligated to the Km^r cartridge. Several *Ava*I sites are present in the 11.8-kbp *Hin*dIII fragment (not shown), so several deletions were obtained. Strain 306 is shown as an example. This strain grows normally in minimal medium, indicating that no essential genes were deleted. Its Nif$^-$ phenotype is complemented by pRPA8, which contains only the copy I *nifHDK* operon[7], so there are no other *nif* genes deleted in strain 306.

answer. We would like, however, to discuss two possibilities: first, that the extra copies are pseudogenes and, second, that they are activated in conditions different from those used here.

The first model implies that the extra sequences are permanently silent, which might be expected for evolutionary remnants from a process of lateral diffusion of *nif* genes in nature[12]. The process of activation to produce the pseudorevertants would create a promoter in front of the coding region(s) of one or more copies, or it would consist of mutations which 'repair' the DNA sequence so as to produce active products, or both.

The second possibility is that the extra copies are functional genes which become activated in growth conditions different from those used here. This model would predict that the nitrogenase encoded by the extra copies has properties (such as ammonia switch-off, substrate affinity, cofactor requirements and regulation) different from copy I nitrogenase, and that the cell has the ability selectively to induce different copies according to varying environmental conditions. Pseudorevertants in this case would be mutants in the activation control mechanism. *R. capsulata* can grow and fix nitrogen anaerobically in the dark, provided a strong oxidant (such as dimethyl sulphoxide or trimethylamine oxide) is present in the medium[13]. However, these compounds are not present in natural environments in a concentration high enough to sustain growth. *R. capsulata* is constantly challenged by changing environmental factors, including interactions with other microorganisms, and it might be very difficult or impossible to reproduce these situations in the laboratory. A variation of this model is that the extra copies are actually silent, but a controlled gene rearrangement can bring genes or segments of genes to the copy I region, resulting in the expression of genes whose products have properties different from those of copy I. The phenotypic reversion of strain 1051 to Nif$^+$, Km^s cells could be the consequence of such a process. These possibilities can be distinguished by sequencing and by characterization of the *nif* gene products in the pseudorevertants.

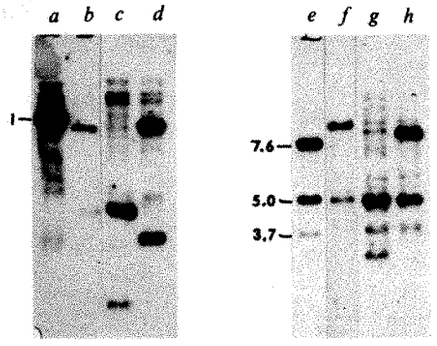

Fig. 4 Characterization of insertion and deletion mutations by Southern hybridization. Total DNA from the following strains was digested with *Hin*dIII (lanes *a–d*) or *Eco*RI (lanes *e–h*): SB1003, lanes *a* and *e*; 1051, lanes *b* and *f*; 306, lanes *c* and *g*; DN51, lanes *d* and *h*. The probe in each case was pRPA5, containing copy I *nifHDK* sequences. Strain 1051 contains the 2.4-kbp Km^r cartridge inserted in *nifH* of copy I (Fig. 3). The cartridge contains a *Hin*dIII site, leading to the two bands seen in lane *b* of 9.9 and 4.3 kbp. Lane *f* shows the 7.6-kbp *Eco*RI fragment increased to 10 kbp by the insert. Strain 306 contains two *Hin*dIII fragments of 4.4 and 2.8 kbp, while the 7.6-kbp *Eco*RI fragment is replaced by one of 3.0 kbp. These changes result from a deletion of 7 kbp and insertion of the 2.4-kbp Km^r cartridge (Fig. 3). Strain DN51 shows two *Hin*dIII fragments of 10.1 and 3.3 kbp, while the 7.6-kbp *Eco*RI fragment is increased to 9.25 kbp. These changes result from a 750-bp deletion and insertion of the Km^r cartridge (Fig. 3).

Methods: Pseudorevertants were isolated as follows: The Km^r Nif$^-$ strains were grown overnight aerobically in RCVB minimal medium at 35 °C[22]. 0.1 ml of these cultures was inoculated into 10 ml of RCVB-NF (nitrogen-free) medium, and grown overnight aerobically at 35 °C to exhaust nitrogen completely. Cells were washed twice with RCVB-NF and approximately 10^9 cells were placed in a 10-ml screwcap tube totally filled with RCVB-NF medium. These cultures were incubated until turbidity was observed (1–2 weeks). Cells were then streaked on RCVB-NF plates and incubated until 2-mm diameter colonies formed (3–4 days). The Km resistance phenotype was tested by replica plating onto RCVB and RCVB-Km. Strain 1051 gave two kinds of pseudorevertants: Km^r (R1051r) and Km^s (R1051s). Only Km^r Nif$^+$ revertants were isolated from the deletion strains. To test nitrogenase activity, cells were grown overnight photosynthetically in RCVB, washed three times with RCVB-NF, resuspended in RCVB-NF and incubated photosynthetically for 8 h before determining acetylene reduction activity[23].

This work adds one more example of bacterial gene families. *Rhizobium phaseoli* has reiterated *nif* sequences[14] and the cyanobacteria *Anabaena*[15] and *Calothrix*[16] have more than one copy of the *nifH* gene. Extra copies of structural genes other than *nif*, of which only one is normally expressed, have been described in other bacterial species. There are two non-identical copies of the spore coat protein gene of *Myxococcus xanthus*[17], separated by a 1.2-kbp spacer. Only the downstream gene that codes precisely for the sequenced coat protein is expressed. A similar situation was found in *Caulobacter crescentus*: of at least three genes that could code for flagellin, the major flagellar protein, only one is normally expressed (N. Agabian, personal communication).

We thank Peter Lammers, Helen Revel, Steven J. Robinson and Nilgun Erekun Tumer for helpful comments. This research was supported by PHS grant GM 21823 and, in part, by a postdoctoral fellowship to P.A.S. from the National Institute of General Medical Sciences.

Transposition of Tn*554* does not generate a target duplication

Ellen Murphy & Sven Löfdahl*

Department of Plasmid Biology, Public Health Research Institute of the City of New York Inc., New York, New York 10016, USA

Transposable elements from prokaryotic and eukaryotic organisms are discrete DNA segments bounded by inverted or directly repeated sequences that insert into non-homologous DNA in a reaction that is independent of the general recombination functions of the host. The mechanisms proposed generally involve a staggered double-stranded scission of the target DNA, ligation to the nicked ends of the transposable element, and replication of the element, resulting in the generation of a directly repeated oligonucleotide target sequence flanking the new copy of the element[1–3]. Most transposons have a relatively low degree of target site specificity coupled with a low insertion frequency. Tn*554*, a *Staphylococcus aureus* transposon which specifies resistances to erythromycin and spectinomycin, displays an unusually high degree of insertion specificity. Tn*554* transposes with high efficiency to a unique ('primary') site in the *S. aureus* chromosome[4,5] and only rarely ($<10^{-6}$ per transductant) to other, secondary sites[6]. We report here the nucleotide sequences surrounding the junctions of Tn*554* in three independent 'primary' insertions and two 'secondary' insertions of the transposon. Two unusual features are revealed: first, the termini of Tn*554* contain neither inverted nor directly repeated sequences. Second, transposition of Tn*554* does not generate the short direct repeats of the target DNA that are characteristic of other transposable elements. These results suggest that the mechanism of Tn*554* insertion may be significantly different from that of other transposons.

Previous blot hybridization experiments (ref. 5 and unpublished data) indicated that insertion of Tn*554*, in each of 25 cases examined, occurred in the same location in the *S. aureus* chromosome, within the limits of resolution of this method. To determine the insertion specificity at the nucleotide level, the sequences of several independent transpositions of Tn*554* into the chromosomes were determined. The following strategy was used to obtain multiple, independent insertions of Tn*554* in the primary target. The transposon was first cloned from the *S. aureus* chromosome into *Escherichia coli* (Fig. 1). The flanking chromosomal sequences contained on this plasmid were then used as a probe to screen for a recombinant plasmid containing the target region from a Tn*554*-negative strain, RN450. The chromosomal insert was then recloned into a *S. aureus* vector (pRN8057) and this construct, pEM9605, was used as a target for transposition of Tn*554*. This method was used effectively

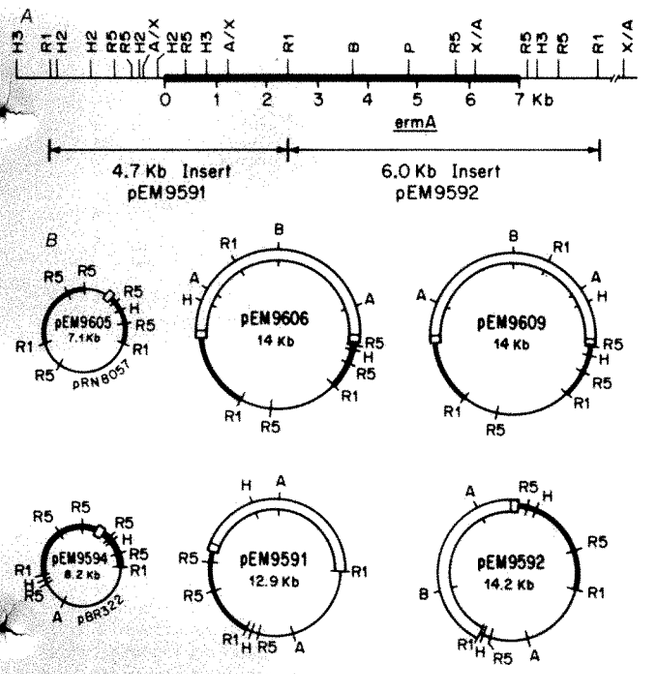

Fig. 1 *A*, Restriction map of Tn*554* and flanking chromosomal DNA. Thick line, Tn*554*; thin lines, flanking DNA. Enzymes are: A, *Aval*; B, *Bgl*II; H2, *Hpa*II; H3, *Hin*dIII; R1, *Eco*RI; R5, *Eco*R5; P, *Pst*I; X, *Xho*I. *B*, Restriction maps of Tn*554*-containing clones. Clones containing the primary (chromosomal) site sequences were obtained as follows: high molecular weight DNA from *S. aureus* strain RN2864 (Tn*554*$^{+}$) was digested with *Eco*RI and the cleaved DNA fractionated on a 10–30% neutral sucrose gradient. Fractions were collected and aliquots loaded onto a 0.7% agarose gel; those containing DNA in the range of 3–7 kb were pooled, the DNA was ethanol-precipitated, and ligated to *Eco*RI-cleaved, alkaline phosphatase-treated pBR322. This preparation was used to transform *E. coli* HB101 with selection for carbenicillin resistance. Transformants were transferred to nitrocellulose filters for colony hybridization[20], using as a probe a 4.9-kb *Aval* fragment from pRN4177, a secondary-site insertion of Tn*554*[6]. As Tn*554* contains a single *Eco*RI site, clones were isolated that contained either the left (pEM9591) or right (pEM9592) half of Tn*554*, as indicated above. The latter carries the Em^{r} locus, which is expressed in *E. coli*. A clone containing the primary chromosomal insertion site (but lacking Tn*554*) was obtained similarly, using *Eco*RI-cleaved DNA from RN450, a standard laboratory host which does not contain Tn*554*. Sucrose gradient fractions containing DNA of the predicted size of the *Eco*RI fragment (3.8 kb) were used for the ligation. The probe for the colony hybridization was the *Eco*RI insert from pEM9592, containing the right half of Tn*554* and 1.5 kb of flanking chromosomal DNA. Positive colonies contained a plasmid with a 3.8-kb *Eco*RI insert which matched the predicted restriction map of the target region. The 3.8-kb insert was subsequently recloned onto pRN8057, a temperature-sensitive derivative of the tetracycline resistance plasmid pT181, and transferred back to *S. aureus* (namely pRN9605).

for transposon Tn*7*, which exhibits an insertion preference for the *E. coli* chromosome that is similar to that of Tn*554*[7,8].

Insertions into pEM9605 were obtained by transduction, using as donors a strain having any one of five penicillinase plasmids containing Tn*554* in a secondary site. We have previously observed that Tn*554* transpositions obtained in this manner are usually associated with loss of the donor plasmid[6]. Erythromycin-resistant (Em^{r}) transductants were therefore screened for the absence of the donor plasmid markers (cadmium and penicillin resistances) and their plasmid contents analysed on agarose gels. Transductants fell into three classes: those containing only the 7.1-kilobase (kb) target plasmid pEM9605 and a chromosomally inserted Tn*554*, those containing only a 14-kb plasmid resulting from the transposition of Tn*554* into pEM9605, and those containing plasmids of various

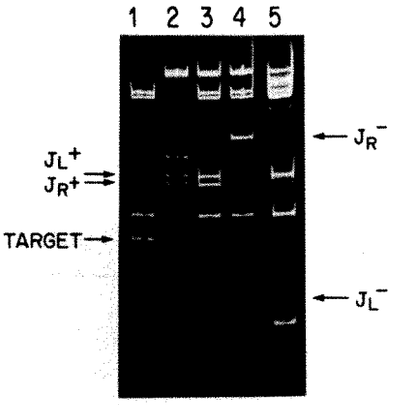

Fig. 2 Restriction analysis of transpositions into pEM9605. Plasmid DNA was prepared as described previously[21], cleaved with *Eco*RV and fractionated on a 5% polyacrylamide gel. Lane 1, pEM9605 (target); lane 2, pEM9595; lane 3, pEM9606 (pRN4176→pEM9605, (+)); lane 4, pEM9609 (pRN4177→pEM9605, (−)); lane 5, pEM9613, a deleted derivative from the cross ϕ11::Tn*554*→pEM9605. *Eco*RV junction fragments J_L^+ and J_R^+, for the (+) insertion, are approximately 1,200 and 980 bp, respectively; for the (−) insertions they are 402 bp (J_L^-) and approximately 1,800 bp (J_R^-); the *Eco*RV restriction fragment containing the Tn*554* target site is ~550 bp long. (Restriction maps of pEM9605, pEM9606 and pEM9609 are shown in Fig. 1*B*.)

intermediate sizes, representing deleted derivatives of pEM9605::Tn*554* insertions. As reported for Tn*7* (ref. 7), transposition into the cloned site does not seem to be as efficient as insertion into the chromosome itself.

Restriction analysis of plasmid DNA from these transductants indicated that Tn*554* inserted into the target fragment present in pEM9605 in the same location into which it inserts in the chromosome (Fig. 2). However, in contrast to the chromosomal insertions, which are orientation and site-specific, insertions into pEM9605 were recovered in both orientations. Recombination between flanking homologous sequences cannot account for the observed orientation specificity of the chromosomal insertions, as this specificity is maintained in the absence of flanking homology (that is, from non-homologous donors) as well as in the *recA* host[5].

Most of the plasmids containing Tn*554* insertions in the same orientation as in the chromosome (designated '+') were structurally unstable and could be detected only in the primary transductant colonies; these gave rise to deleted derivatives that had preferentially lost most of Tn*554*. Insertions into pEM9605 in the opposite orientation (designated '−') and some of the (+) orientation insertions, were stable. It is likely that insertions occurred with equal frequency in both orientations, but that only one class is recovered. Differences between the sequences present on the chromosome beyond the cloned region, and on the vector pRN8057, might account for the instability of the (+) transpositions in pEM9605. Note that the 3.8-kb insert of pEM9605 could itself be cloned in only one orientation into pRN8057; repeated efforts to reverse the orientation of the target fragment failed. In addition, experiments using a host strain carrying a chromosomal deletion of the primary insertion site suggest that the instability may be a consequence of recombinational events between the chromosome and the cloned chromosomal sequences (M. Bastos and E.M., unpublished data).

The nucleotide sequences of the junctions of several independent Tn*554* insertions are shown in Fig. 3. Two unusual features of the Tn*554* junctions are apparent. First, the ends of Tn*554* lack any direct or inverted repeat sequences. Second, insertion of Tn*554* does not generate a repeat of the target DNA. These results contrast with all other known transposable elements except for bacteriophage Mu, which also has asymmetric ends, but which generates a 5-base pair (bp) duplication[9]. Tn*7*, although similar to Tn*554* in its insertion specificity with respect

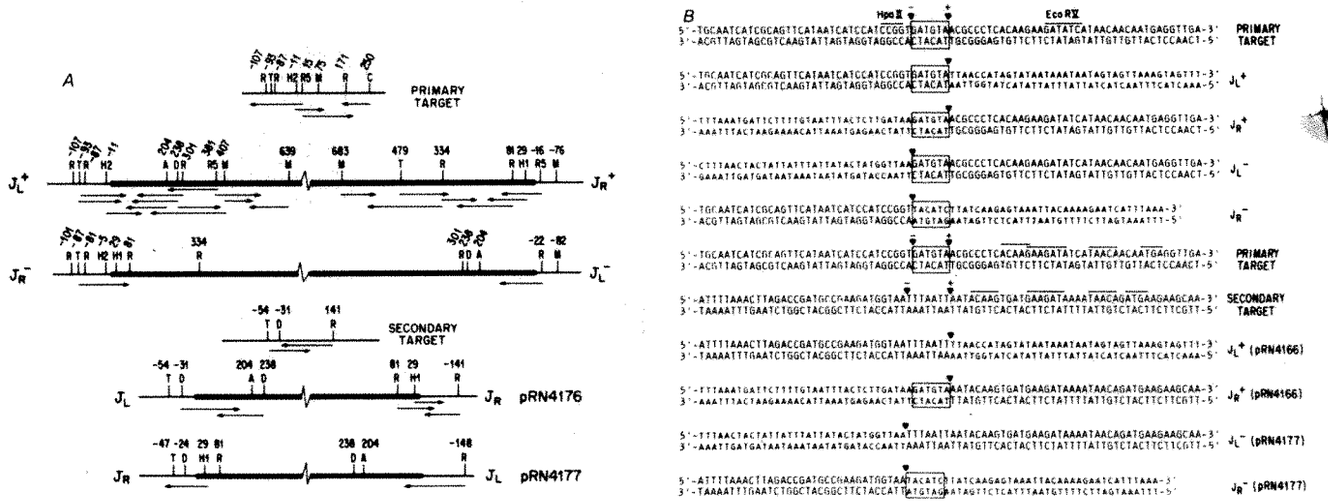

Fig. 3 ***A***, Strategy for sequencing the Tn*554* junctions. Thick lines represent Tn*554* DNA; thin lines, flanking sequences. Fragments were sequenced in the direction of the arrows. DNA fragments isolated from acrylamide gels were 5′-end labelled with polynucleotide kinase (P-L Biochemicals) and cleaved with a second restriction enzyme or strand-separated. Sequencing was done by the method of Maxam and Gilbert[22]. The chromosomal target sequence was determined twice using pEM9594 and pEM9605, which carry the 3.8-kb *Eco*RI target fragment cloned into pBR322 and pRN8057, respectively. pEM9591 and pEM9592 contain the chromosomal junctions J_L^+ and J_R^+, respectively, cloned directly from the Tn*554*-containing *S. aureus* chromosome (RN2864); pEM9606 and pEM9607 carry insertions of Tn*554* in the same orientation as the chromosome (+), into the 3.8-kb target fragment cloned in pEM9605. The junctions of two (−) orientation insertions were obtained from pEM9609 and pEM9612. The sequences of the secondary-site target and insertion junctions were derived from pRN4176, pRN4177 and pEM6271; the latter contains a 2.5-kb *Bgl*II fragment containing the targets for the pRN4176 and pRN4177 insertions. Enzymes are: A, *Alu*I; C, *Cfo*I; D, *Dde*I; H1, *Hin*fI; H2, *Hpa*II; M, *Mbo*I; R5, *Eco*RV; R, *Rsa*I; T, *Taq*I. ***B***, sequences of the Tn*554* insertion junctions. The terminal 40 bp of Tn*554* at each end and 80 bp of the target DNA are shown. Homology between the primary and secondary target sites is indicated by the lines over the sequences. The GATGTA sequence derived from either Tn*554* (smaller typeface) or the target DNA (larger typeface) is boxed.

to the chromosome, also provokes a 5-bp target repeat[10]. In these respects Tn*554* is more similar to temperate bacteriophages such as λ.

Sequences were obtained for the chromosomal insertion that was cloned directly from the *S. aureus* chromosome, for two independent (+) insertions of Tn*554* into pEM9605 (pEM9606 and pEM9607), and for two (−) insertions into pEM9605 (pEM9609 and pEM9612). The junctions of two secondary site penicillinase plasmid insertions (pRN4176 and pRN4177) were also sequenced. All three of the (+) insertions sequenced were found to have inserted between the same nucleotide pair, 3′ to the sequence 5′-GATGTA-3′. This sequence is also present at the right terminus of Tn*554*. The two (−) insertions sequenced are just 5′ of this same sequence, six nucleotides upstream from the site of the (+) insertions. The two secondary-site insertions are 7 bp apart, and in opposite orientations from one another; while they are separated by the sequence TTTAATT, there is a near-match (GATGGTA) to the GATGTA, immediately 5′ to the pRN4177 site (Fig. 3*B*). However, this sequence is unlikely to be sufficient to account for the insertional specificity, as it would be expected to occur approximately 1,000 times in the *S. aureus* chromosome, assuming that these sequences are not restricted. Comparison of the primary and secondary targets revealed some homology 3′ to the insertion sites (Fig. 3*B*); however, these sequences differ greatly in their A+T content: ~47% and 76% for the 30 bp surrounding the primary and secondary sites, compared with 65% for *S. aureus* DNA[11]. The Tn*554* termini are themselves highly A+T-rich (≥80%), a fact which may contribute to the efficiency of transposition, as A+T-rich DNA is highly recombinogenic.

Earlier data concerning excision of Tn*554* (ref. 4) had led to the suggestion that Tn*554* inserts and excises like bacteriophage λ[12], using a free circular intermediate. The presence of the common GATGTA sequence at both the right end of Tn*554* and at the site of insertion, and the absence of a target duplication, are consistent with this hypothesis. However, if Tn*554* inserted via recombination between the 'common core' sequence GATGTA, integration would of necessity be orientation-specific and would not account for the insertions in the (−) orientation into pEM9605 or for the opposite orientations of the two secondary-site insertions. Our sequence data do not rule out the possibility of a circular intermediate assuming that the strands can be cut and rejoined on either side of the GATGTA sequence. Recent experiments suggest that the donor replicon may not be recovered following transposition (I. Edelman and R. Novick, personal communication); the simplest, but not the only, mechanism that could account for these results is a conservative, double-stranded transfer of Tn*554* to a flush, double-stranded break in the recipient DNA molecule. Conservative mechanisms have been suggested for the transposition of Tn*5* (ref. 13) and for the initial insertion of bacteriophage Mu[9,14,15]. The Mu prophage is flanked by 5-bp repeats[16,17] but the mature bacteriophage apparently is not: it is probable that prophage insertion and replicative transposition use two different pathways[9,18,19].

We thank Dr Carol J. Lusty for help with the DNA sequencing and Leslie Huwyler for technical assistance. This work was supported by NIH grant GM27253 to E.M.

Sedimentation in Loch Earn and Loch Lubnaig, Scotland

IN their paper about sedimentary features associated with slumping in Loch Earn and Loch Lubnaig, McManus and Duck[1] indicate that there is no prior record of the use of sonar devices in lakes for the investigation of "subaqueous landforms". This is a curious statement given our[2] earlier reported work in their own field area and the extensive surveys of the Canadian Centre for Inland Waters in for example, the Great Lakes (see ref. 3), where acoustic techniques have become standard for mapping both lakebed and sub-bottom landforms, whose recognition is regarded as a normal prerequisite for any engineering undertaking.

While McManus and Duck[1] recognize that their observed slumps occur at depths below the influence of surface water waves, they do not consider the possibility that longer period waves, such as seiches or internal waves, may influence bed forms. It is instructive to investigate the theoretical seiche[4] for any lake under sedimentological investigation to see if water velocities expected at the lakebed may be great enough to cause sediment movement. I have done this for a water body of rectangular cross-section (length 2,500 m, depth 30 m) as a crude model of the Stank Basin[5] of Loch Lubnaig and conclude that a water particle velocity of 5 cm s^{-1} is possible for a seiche of only 0.1-m amplitude, the period of oscillation being ~5 min. Seiche observations by Gill[6] on Llyn Gwellyn, a lake of comparable size to the Stank Basin, suggest that a real seiche would be of longer period than the approximate theory predicts, but that particle velocities at the base of the water column would still be sufficient to transport silts and finer grains (Graf and Acaroglu[7]) even if the seiche amplitude were only a few centimetres. We[2] have observed three sediment waves or mounds in the bed of the Stank Basin. They rise, with gradients of 1:5, to a height of 5 m above the general level of the fine lakebed sediment, which is itself no more than 5 m thick. The sediment waves are symmetrical and show layering which parallels the sediment–water interface. Such layering and symmetry would not arise from slumping, but could be produced by a seiche-driven oscillatory water current. McManus and Duck[1] have drawn attention to the effect that sediment disturbance from slumping will have on the interpretation of lakebed sediment cores retrieved for palaeomagnetic or palaeoecological purposes. Disturbance in the manner I propose will be a more subtle effect because of the presence of seemingly undisturbed layers.

In Scottish lochs, the use of modern acoustic equipment (with the exception of its largely ludicrous use in Loch Ness) has been neglected. This is not the tribute that Murray and Pullar[7] would have wished. As well as conventional sidescan and profiling records, sediment acoustic velocity determinations are required[8,9] to help assign proper depth scales and to assess sediment gas content, cited by Monroe[10] as an important factor in causing slumping. I hope that McManus and Duck[1] and others will receive support to extend their work to other lochs and perhaps to map more completely the mounds in the Stank Basin and to verify if they are indeed associated with seiche activity induced by the winds howling down the glen at Ardchullarie Mor.

DUCK AND MCMANUS REPLY—We welcome the comments of McKay concerning our recent contribution[1]. He is correct to draw attention to sonar work in the North American Great Lakes. In view of their enormity these water bodies behave as inland seas and are not directly comparable with even the largest of the Scottish lochs.

Our contribution[1] specifically referred to sidescan sonar surveys and not to the use of sonar devices in general. The principal work reported was undertaken on Loch Earn and mention was made of Loch Lubnaig to illustrate that the subaqueous landforms recognized are not mere curiosities confined to one water body. We have since detected them in other lochs.

We were unaware of the boomer seismic work of McKay and McEwen[2] in Loch Lubnaig as their brief abstract was published in a Canadian journal not known for its contributions to Scottish environmental studies. The report of sediment waves or mounds in the Stank Basin[2] is interesting but, despite re-examination of sonographs and echograms[3], we have been unable to confirm their presence due to lack of information regarding their position or orientation. However, marginal spurs are recognized extending into the basin floor from the bounding slopes.

Seiches or internal waves may indeed influence loch bedforms. However, as yet, we have insufficient hydrodynamic data to corroborate this. Furthermore we have reservations about the seiche-associated current velocities calculated by McKay for Loch Lubnaig. Although we have not undertaken seiche observations in the loch there is good reason to believe that the 0.1-m surface seiche amplitude used in McKay's model, and to which the horizontal current velocity is proportional[4], is excessively large. Chrystal[5] demonstrated that seiche activity is poorly developed in Loch Lubnaig due to its shallow nature (mean depth, 13 m), its very irregular bottom and its orientation across the path of atmospheric disturbances. During a 6-week period only four instances of definite, but short-lived, seiche activity, with a period of about 24 min, were recognized[5]. For most of the period "... nothing was found but wind embroidery and sub-permanent wind denivellation, such as would be naturally expected in a shallow lake"[5]. Moreover, the maximum seiche amplitude observed by Chrystal[5] (Fig. 22) was only about 0.5 cm. On the basis of McKay's model for the Stank Basin the maximum current velocity, at a seiche node, associated with such activity would be less than 0.3 cm s^{-1}. Average current velocities would be about half this value and tend to die away rapidly with time[6]. Thus currents resulting from surface seiches are unlikely to be responsible for the bedforms described.

To our knowledge the thermal behaviour of Loch Lubnaig has not been investigated. However, it is likely that internal wave (internal seiche[7]) activity will occur in association with summer stratification. Horizontal current velocity components generated by such water movements are known to be up to five times greater than those associated with corresponding surface seiches[8,9]. Moreover, these currents can persist for several days[8]. Hence it is possible that internal waves may have a role in the formation of the structures recognized by McKay and McEwen[2], perhaps in the manner advocated by Mortimer[10].

Control of fertility in red deer

LOUDON *ET AL.*[1] have recently invoked a suckling-mediated mechanism for the control of fertility in red deer hinds. We suggest that their emphasis on the role of prolactin is not justified by their data and that other explanations are equally likely.

Although plasma prolactin concentrations are positively associated with the frequency of suckling[2], the authors fail to show a significantly higher plasma prolactin level after 80 days, between groups of hinds on low versus high planes of nutrition, despite the persistence of high suckling frequencies in the former. There is a minimum lag of some 30 days separating this latest detection of a difference in plasma prolactin levels between the groups and the earliest possible conception on day 110—when the stag was introduced. It is questionable as to whether there would be an ovulation-inhibiting effect of increased plasma prolactin levels this far in advance of ovulation, even if, as has been suggested[3], such an effect were to operate on the follicular stage of the 18.3 day oestrous cycle[4]. This is assuming that prolactin has a causal influence on oestrus cycle activity which itself remains in doubt[5].

Loudon *et al.* do not attempt to separate from the suckling data the confounding effect of differences in mean body weight between the two groups. It is well established that body weight not only influences fertility rates but may also affect the onset of oestrus in mammals[6]. In farmed red deer small hinds calve later than heavy hinds: a 1 kg increase advancing calving by between 0.3 and 1.0 days (ref. 7 and A.S.I. Loudon, personal communication). Furthermore, in the wild the average non-lactating hind calves approximately 2 days earlier for every 1 kg increase in mean autumn body weight[8]. Therefore a 4.1 kg difference in mean body weights between the two groups could explain the 6.5 day difference in return to oestrus and could be tested with their data. However, even if this is plausible and weight for weight hinds on a low nutritional plane return to oestrus later, this may be for reasons other than lactational control. For example, it is well known that in sheep, which cease lactation many weeks before the rut, body condition interacts with the plane of nutrition immediately before breeding[9]. At a given weight individuals that are rapidly improving in condition, as might be expected in the group of hinds on permanent grass pasture, show earlier ovulation and higher ovulation rates.

In summary, Loudon *et al.* concur with at least one other study in failing to show any influence of the plane of nutrition on plasma prolactin levels during or immediately before the onset of the reproductive period[10]. As a consequence, they have little reason to invoke elevated levels of prolactin as a mechanism delaying conception in poorly nourished hinds. Finally, by not controlling in any way for maternal body weight and/or condition, the major confounding variable is not eliminated nor its contribution to the observed effect even brought into question.

LOUDON *ET AL.* REPLY—In our paper we drew attention to the influence of pasture type on the milk yield, suckling patterns and fertility of red deer hinds. We were alerted to the physiological implications of the differences in suckling pattern when we considered our data on prolactin. These data, in common with a number of other studies, showed that prolactin levels were correlated with suckling frequency. At no point in our paper did we suggest that prolactin *per se* was ultimately involved in the regulation of fertility in red deer. Indeed we would suggest that in seasonally breeding mammals such as deer and sheep prolactin may have little influence on fertility. Thus, sheep treated with bromocriptine to block the normal high levels of prolactin in mid-summer resumed fertility at an identical time to untreated control sheep[1,2]. Thus although prolactin may have an important function in regulating fertility in some mammals including humans, we agree with Albon and Iason that there is little evidence that it may be directly important in the case of red deer.

We know of only one study that attempted to control female weight, food intake, milk yield and offspring growth rate while manipulating suckling frequency. In this study, ewes compelled to suckle their offspring twice a day resumed oestrous activity at an earlier date than those permitted to suckle five times a day[3]. We acknowledge that there is clear evidence that the body condition of non-lactating sheep prior to mating has an effect on their fertility but suggest that in the cases of wild mammals, including red deer, which, unlike sheep, frequently suckle their offspring through the mating period, the pattern of suckling activity may have a profound effect on their subsequent fertility. Body weight *per se*, like prolactin, simply correlates with differences in return to oestrus in red deer. We are unable to attribute differences in body weight between the two groups of hinds to differences in body condition or differences in gut fill associated with the complex effects of grazing different grass pastures.

Matters Arising

Matters Arising is meant as a vehicle for comment and discussion about papers that appear in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted. Neither contribution nor reply (if one is necessary) should be longer than 500 words and the briefest of replies, to the effect that a point is taken, should be considered.

ISBN 3-540-11665-6

Tumorviruses are widely used as tools to analyze the cellular processes which lead to malignant transformation. One of the most intriguing and important aspects of tumorvirus-cell interactions is the relationship between the differentiated state of the host cell and its susceptibility to infecting viruses. This book presents a series of reviews dealing with experimental systems in which only cells at a specific stage of differentiation are permissive for viral transformation and/or replication.

AQUATIC TOXICOLOGY

edited by **J.O. Nriagu,** *National Water Research Institute, Burlington, Canada*

This emphasizes the effects of aquatic toxicology (pollutants) on aquatic biota and discusses the physiological and biochemical effects of aquatic pollutants on aquatic animals. It includes coverage of the most current methodologies for detecting/analyzing toxicant-induced effects. It describes and analyzes toxic effects at the subcellular/cellular, tissue, organism, and community levels.

WASTES IN THE OCEAN, Volume III

Radioactive Wastes in the Ocean

edited by **P.K. Park,** *National Oceanic and Atmospheric Administration;* **D.R. Kester; I.W. Duedall,** *S.U.N.Y., Stony Brook;* and **B.H. Ketchum,** *University of Rhode Island*

This is a comprehensive guide to evaluating methods of disposing radioactive wastes into the ocean, reviewing current research and selected case studies. It covers the interrelationship of oceanographic properties and processes to waste disposal practices and examines the behavior and fates of radioactive wastes in the marine environment, their effects on ocean life, and implications for human health. Strategies for determining optimal site selection, packaging, and engineering design of waste disposal are presented.

Environmental Science and Technology: A Wiley-Interscience Series of Texts and Monographs.

January 1984 — 544 pages
0471 09770 5 — $97.95/£69.95

TREES AND NETWORKS IN BIOLOGICAL MODELS

by **N. MacDonald,** *Department of Natural Philosophy, Glasgow University*

The first half of this book deals with the description of abstract networks, using the terminology of graph theory. Part I is concerned with the characterisation of overall properties of networks in terms of appropriate numerical indices, and Part II with stability of steady states and oscillations in networks. The second half (Part III) gives the first available general review of the description, biophysics and simulation of real branching structures, with illustrations from botany, zoology and the physiology of arteries, lung airways and nerve cells.

MARINE ECOLOGY

Volume V: Ocean Management, Part 2
Ecosystems and Organic Resources

edited by **O. Kinne,** *Biologische Anstalt Helgoland Zentrale, Hamburg, West Germany*

MARINE ECOLOGY provides an exhaustive, systematic exposition summarizing and evaluating the information obtained thus far on living systems in the sea and in littoral areas. It has been conceived with the increasing number of individuals in mind who are professionally concerned with life in the marine environment — especially investigators, teachers and students.

Series: Marine Ecology: A Comprehensive, Integrated Treatise on Life in Oceans and Coastal Waters, Volume V Part 2.

November 1983 — 466 pages
0471 90159 8 — $85.00/£45.00

EQUILIBRIA, NONEQUILIBRIA, AND NATURAL WATERS, Volume II

by **R.M. Pytkowicz,** *Oregon State University*

This book develops aquatic chemistry, geology, and hydrology from first principles, and applies them to the aquatic environment and complex solutions found in oceans, rivers, lakes, and laboratories. It examines processes in natural waters within the framework of thermodynamics and heterogeneous kinetics and presents serious research applications. It covers acids, new solid-solution equilibrium work, complexes, redox reactions, the geochemistry of trace metals, and gas-water interactions.

November 1983 — 372 pages
0471 89111 8 — $57.45/£40.95

THE GLOBAL BIOGEOCHEMICAL SULPHUR CYCLE, SCOPE 19

edited by **M.V. Ivanov,** *Deputy Director, Institute of Biochemistry and Physiology of Microorganisms, USSR Academy of Sciences* and **J.R. Freney,** *CSIRO Division of Plant Industry, Canberra City, Australia*

This book focuses attention on the poorly investigated problems of the global biogeochemical sulphur cycle and opens the way for further study. It examines the possible long term effects on the stratospheric sulphate layer and the consequent effects on climate.

Series: SCOPE Report, Number 19

December 1983 — 496 pages

Super theories

Abdus Salam

Supersymmetry and Supergravity. By Julius Wess and Jonathan Bagger.
Princeton University Press: 1983. Pp.180. Hbk $40, £34.50; pbk $12.50, £10.90.

SUPERSYMMETRY — a possible symmetry between bosons (particles of spins zero or one or two, obeying Bose statistics) and fermions (particles of spins ½ or 3/2 obeying Fermi–Dirac statistics) — is an incredible postulate. It could have been made at any time after 1935, when the canons of quantum theory of fields were established. We had, however, been brought up from the kindergarten to think of spin zero (or spin one or spin two) bosons as intrinsically different from spin ½ (or spin 3/2) fermions. The fermions are individualists. In accordance with Pauli's exclusion principle, no two identical fermions could congregate at the same space point. In contrast the bosons are gregarious. They like to congregate and seek each other's company at the slightest provocation. How could one even try to place such different objects in the same multiplet of a possible symmetry group? In what sense could there be a symmetry between quanta of matter (typically fermions) and quanta of forces (typically bosons)?

In 1971, in the USSR, Golfand and Lichtman first discovered that one could, if one wished, introduce a fundamental symmetry between bosons and fermions — notwithstanding their intrinsic differences. The significance of their work was totally missed, however, and ignored until 1973 when this same symmetry was rediscovered by Julius Wess and Bruno Zumino working in the West. Even then (and despite the self-evident elegance of the symmetry, the relative freedom of supersymmetrized Lagrangians from field-theoretical infinities, as well as the guaranteed positivity of the energy) there was no direct evidence of the symmetry's existence at energies available in laboratories and supersymmetry remained a minority interest. The esoteric nature of the subject was reflected by the complete absence of relevant textbooks; conference proceedings and excellent review reports, yes, but no pedagogical material.

Now, after several years of increasing interest, a new generation of texts has begun to appear. Wess and Bagger's *Supersymmetry and Supergravity*, based on a course of lectures given by the senior author at Princeton, is one of the first. To assess the book, what it contains and what it chooses to leave out, it is necessary to consider the recent history of ideas in this field.

Two of the early developments concerned, first, the recognition of the existence of the so-called extended supersymmetries (N = 2, 3, 4 . . . 8) where internal symmetries are married to simple supersymmetry (N = 1); and second, the superspace and the superfield method of exhibiting N = 1 supersymmetry in field theory. The simple N = 1 supersymmetry admits of two spin zero particles being grouped together with one spin ½ Majorana particle into a single "supermultiplet". All these particles must possess the same mass. The N = 1 superfield is a field-function which describes this entire set of particles; the field is defined in "super-space" which is space-time manifold augmented with an additional fermionic coordinate. The extended N = 2 supersymmetry admits of a supermultiplet with four spin zero and two spin ½ objects. The super-space this supermultiplet would exist on would admit of *two* fermionic coordinates. And so on for N = 3, 4, . . . , this sequence ending finally with the N = 8 supersymmetry — the so-called maximal supersymmetry — which would group together the following into its fundamental supermultiplet: one spin two, eight spin 3/2, twenty-eight spin one, fifty-six spin ½ and seventy spin zero massless objects.

During 1974–1975 renormalizable supersymmetric theories of spin ½ and spin zero objects were elaborated, as were supersymmetric theories of spin one and spin ½ particles, describing gauge quanta and their supersymmetric partners, the gauginos. Then, in 1976, the prize problem of supersymmetrizing gravity was solved. This was the prize problem because a gauging of supersymmetry must inevitably lead to a supersymmetrization of Einstein's gravity. The N = 1 "supergravity" which results is a generally-covariant, local, supersymmetric theory of the spin 2 particle (the hypothetical graviton) and of its supersymmetric partner (the still-more-hypothetical gravitino of spin 3/2). The following years were an exuberant period of writing down of theories of extended supergravities (N = 2, 3, 4, 8). With these — and particularly with N = 8 supergravity — a singular hope was born: that particles of spin two and spin one, mediating *all* the four fundamental forces (gravity, electroweak and strong), together with the appropriate spin-zero Higgs needed to break the electroweak and other gauge symmetries, and interacting with "source" matter of spin ½ quarks and leptons, could all be described by the fundamental supermultiplet of the N = 8 theory interacting with itself. This would not only unite the "marble" of gravity with the "base wood" of matter, as Einstein dreamt; in Hawking's eloquent phrase, it would be the "Theory of Everything".

Unfortunately, the spectrum of particles, even in the maximally extended supergravity theory (N = 8) turned out to be inadequate to accommodate the known quarks, leptons and gauge particles. It was also soon recognized that, after gauging, any such theory must contain two coupling constants — the Newtonian constant determining the strength of the gravitational force and an unacceptably large cosmological constant in lieu of the fine structure constant (phenomenologically wrong by factor 10^{120}!). On the technical side too, there were problems. It came to be clearly appreciated that the geometrization of physics, which started with the Einsteinian revolution of associating gravity with the curvature of space-time, would not be complete until supergravities had been described in terms of geometrical entities (super-curvature and super-torsion) in extended space-times — extended with the addition of the new fermionic coordinates on which the requisite superfields depend.

This was the situation in 1981. We had theories which were tantalizingly elegant but technically incomplete; theories which were relevant, but not quite adequate as far as the known low-energy physics was concerned. Since 1981, however, a fresh look has been taken at supersymmetry theories. The motivation for this has come from a new direction — from the so-called hierarchy problem, the problem of disparate mass scales in physics. In particle physics the relevant scale of masses ranges from the mass of the electron (of around 10^{-3} Gev) to the Planck mass associated with Newton's constant of gravity ($\approx 10^{19}$ Gev). The ratio of these two masses is an enormous number of the order of 10^{22}. And if the electronic neutrino is also massive (with an expected mass of the order of 10^{-8} Gev), the range is even more staggering. Dirac pointed out this problem of large numbers a long time ago; he attempted to solve it within the context of his cosmological theories, with a time-varying gravitational constant. Such theories, however, appear not to be favoured by current experiment.

Around 1981, came the realization that at least one aspect of this problem — the radiative stability of the mass ratios — could be resolved using supersymmetric ideas. With this input, suppose one was not too ambitious and did not ask for a Theory of Everything in one go; suppose one were to go back to 1974 and 1975 and try to invent a humble, realistic supersymmetric model of the electroweak or the electronuclear theories only. One would choose to eschew gravity and with it the spin 3/2 superpartner of the graviton. Such a model theory would contain photons and photinos; Ws and Zs, and their superpartners the winos and zinos; it would contain higgs and higginos. It would also contain quarks and quarkinos, and leptons

and leptinos (quarkinos and leptinos would be spinless; photinos, winos, zinos and higginos would carry spin ½). How near to a successful model could one come in this restricted programme?

To be physically realistic, the most crucial further input needed would be a mechanism for supersymmetry breaking. This would generate a mass-difference between the known particles and their (hitherto undiscovered) superpartners, and would explain our inability in not having detected these superpartners so far. A desirable supersymmetry-breaking mechanism should be spontaneous, if only to conform to the pattern of symmetry breakings already familiar in particle physics.

But such a spontaneous supersymmetry breaking (even if it could be simply accomplished) would pose its own problems. It would lead to the existence of at least one massless spin ½ particle — the goldstino. Could this massless fermion be one of the known neutrinos? Alas, the predicted low-energy behaviour of the goldstino turned out to be quite different from that of neutrinos. The goldstino must be suppressed.

Now the only known mechanism to suppress the appearance of the goldstino is to re-introduce the spin 3/2 gravitino, which would absorb the goldstino (super-Higgs effect) and itself become massive. We are inevitably being led back to supergravity, but this time with supersymmetry-breaking as an important new ingredient. This is not a unification of gravity with other forces (electroweak or electronuclear). But it is a triumph nevertheless, in showing that gravity may already be influencing low-energy particle physics.

Models incorporating these ideas were constructed during 1982. The exciting thing is that this type of supersymmetry-breaking (i.e. through the introduction of $N = 1$ supergravity) can also induce a breaking of the electroweak gauge symmetry. The masses of the Ws and the Zs are then a consequence of supergravity and super-Higgs effect! The spin 3/2 superpartner of the graviton is expected to weigh around 300 Gev. The winos and zinos may be lighter than their supersymmetric partners, the recently discovered Ws and Zs. If experiments at the CERN p–$\bar{p}$ collider show that the Ws and the Zs do indeed decay into winos and zinos, the age of supersymmetry will have come. Further evidence for this may be provided by proton-decay experiments, currently in progress. In the supersymmetric models the favourite decay is likely to be the proton decaying into a muon plus a kaon rather than the non-supersymmetric decay into a positron plus pion (searched for hitherto and apparently not found). The future CERN Large Electron–Positron accelerator (now under construction for Z^0 physics) may, in fact, justify itself much more as a supersymmetry accelerator. My own hunch is that this is what will happen.

But even if $N = 1$ broken supergravity theory, in interaction with $N = 1$ supermatter, is indicated by low energy (a few hundred Gev) experiments, this would still not be a Theory of Everything. We would need to bring back the ideas of extended supergravity and in particular of the $N = 8$ extended theory to achieve this. What then of progress in this area?

Here also there have been developments of great potential significance. Extended supergravities are flourishing with the discovery (in 1979) that the maximal $N = 8$ supergravity theory in four space–time dimensions can be recovered from the simple $N = 1$ supergravity in a space–time of eleven dimensions. This is a super-extension of an original idea of Kaluza and Klein, formulated some 60 years ago, in which the following miraculous happening was noted: an Einsteinian gravitational Lagrangian in *five* dimensions is equivalent to the normal Einsteinian Lagrangian in four dimensions plus Maxwell's electromagnetism, when the fifth dimension is "compactified" to a vanishing size. The new version of this — the super-miracle — occurs in eleven dimensions, where the simple ($N = 1$) supergravity gives rise exactly to the $N = 8$ extended supergravity theory in four dimensions, when the extra seven dimensions are suitably shrunken.

But what if the compactification size is finite, albeit smaller than the Planck size (i.e. $< 10^{-33}$ cm)? What effect is the topology of the seven-dimensional "internal" manifold likely to have on the resulting physics? Do such compactifications yield new (broken) supertheories, more in accord with experiment than the original massless $N = 8$ was? This is the search that is currently on in the context of a fundamental Theory of Everything. Some day, it is hoped, this method of attack will embrace and meet the phenomenological approach mentioned earlier.

And what of Wess and Bagger's new book? It is a beautiful exposition of the original ideas of Wess and Zumino in formulating $N = 1$ supersymmetry and supergravity theories, couched in the language of superfields introduced by Strathdee and the reviewer. The use of differential forms in super-space leads to a succinct exposition of ideas of super-torsion and super-curvature. Not discussed, however, are extended supersymmetries, or extended supergravities. There is also no comparative discussion of other approaches to $N = 1$ supergravity (except that of Wess and Zumino); and, of course, there are no phenomenological applications. But within its compass, the book is masterly. Coming as it does from one of the originators of the subject, all serious students of particle physics would do well to acquire a copy. □

Abdus Salam is Director of the International Centre for Theoretical Physics, Trieste, and a Professor in the Department of Physics at Imperial College, University of London.

Working plants for the ecologist

Peter D. Moore

Physiological Plant Ecology II, III and IV. (Vols 12B, C and D of *Encyclopedia of Plant Physiology*, New Series.)
Edited by O.L. Lange *et al.*
Springer-Verlag: 1983. Vol. 12B, pp.747, DM 288, $111.82; Vol. 12C pp.799, DM 298, $115.70; Vol. 12D pp.644, DM 290, $112.60.

THE publication of Vol. 12D in the new *Encyclopedia of Plant Physiology* marks the completion of the section dealing with the essentially ecological aspects of plant physiology. Since the appearance of Vol. 12A, the first in the set (for review see *Nature* **301**, 181; 1983) which dealt largely with the physical environment, there have been two intervening volumes published.

Volume 12B covers two main topics, water relations and carbon assimilation. In fact, most of the photosynthetic material is actually dealt with in 12A and what remains here is closely related to water balance problems, for example the article on the ecological significance of C_4 metabolism by C.B. Osmond *et al.* Here the competitive advantages are considered mainly in connection with drought, though some mention is made of aquatic plants. On the water relations side, subdivision of the subject consists of the various stages of water passage through the plant and also the water balance of individual cells. Of general interest to ecologists are chapters on drought tolerance, flood tolerance, frost-drought and seed germination.

Volume 12C deals mainly with inorganic aspects of plant nutrition and the ecological orientation of material is here very apparent. Limestone and *p*H effects have their own chapter (H. Kinzel), as do metals (H.W. Woolhouse). Microbial studies also receive some attention, with chapters on halotolerance, lichen symbioses, nitrogen fixation and mycorrhiza. That macabre source of interest the carnivorous plant is also given its own chapter (U. Lüttge) and a timely plea is made for a quantitative, systems study of these well-worked but little understood plants.

Interactions between plants and other organisms forms a second theme in this volume, including such topics as parasitism, the ecology of viruses, pollination (a chapter well supplied with chemical information difficult to find in standard texts) and herbivory, where the phenomenon of compensatory growth is given welcome prominence. It is left to E.I. Newman to cover interactions between plants in just one chapter and he tackles this wide subject by concentrating on mechanisms of interference.

The final volume, 12D, is perhaps the

most remarkable in that it extends the coverage of the series far beyond the scope of earlier encyclopaedias of plant physiology. Its subject is the plant component of ecosystems. Beginning with chapters on nutrient cycling in terrestrial, freshwater and marine ecosystems, it focuses on productivity within the major biomes. The aquatic nutrient cycling chapters concentrate upon specific elements, such as phosphorus and sulphur, and the marine account ties in well with the plant-interactions theme of the previous volume by analysing the influence of nutrient levels on phytoplankton diversity.

The productivity chapters feature the technical problems associated with estimates of production and also provide some detailed accounts of the growth models used to describe production processes on a biome scale. The volume closes with chapters reviewing pollution and eutrophication problems, including topical items such as increasing atmospheric CO_2 levels.

Looking back through the physiological plant ecology section of the *Encyclopedia*, one must be impressed by the amount of information which has been pressed into four volumes. The provision of a subject index at the end of the quartet will enable ecologists of all shades to gain rapid access to a wealth of up-to-date, well-reviewed material with extensive bibliographies. Subject overlap and repetition does exist, but is not excessive; omissions are few, though some topics, such as plant competition, deserved more space. Although somewhat bulky, these four books will render redundant about two shelves of older ecology texts, so it is well worth making room for them. □

Peter D. Moore is Senior Lecturer in the Department of Plant Sciences, King's College, University of London.

Fisher from inside

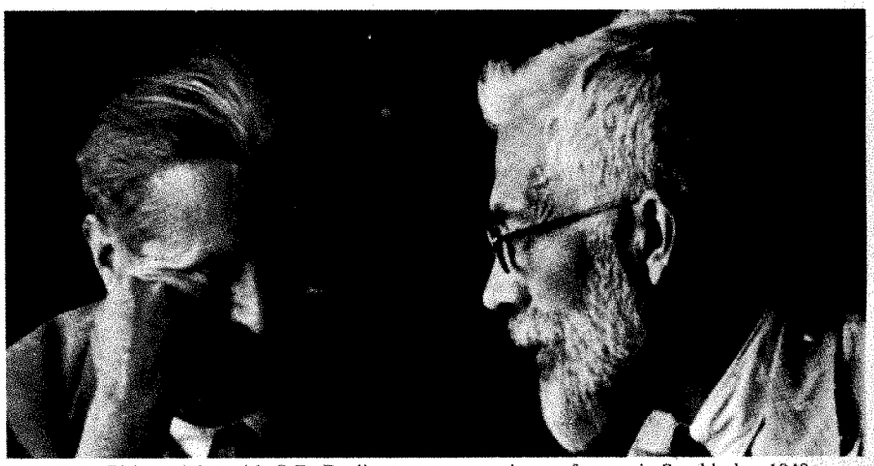
Cedric A. B. Smith

Natural Selection, Heredity and Eugenics.
Edited and introduced by J.H. Bennett.
Oxford University Press: 1983. Pp.306. £17.50, $47.50.

IN a letter to Hooke, Newton wrote "If I have seen a little further it is by standing on the shoulders of Giants". But the pace of scientific advance has accelerated so that, as Gerald Holton is said to have remarked, "We are now uniquely privileged to sit side by side with the giants on whose shoulders we stand".

As a student, I knew a little about mathematical genetics, and was vaguely aware that the major pioneering work had been done by R.A. Fisher, J.B.S. Haldane and Lancelot Hogben. (I was only later to hear of Sewall Wright.) I had a rosy vision of Fisher, Haldane and Hogben frequently discussing, with great excitement, their latest discoveries and plans for the future.

In fact, after the Second World War, fate decreed that I should become a mathematical geneticist, and get to know Fisher, Haldane and Hogben personally (and even, on occasion, sit side by side with them). What immediately became clear was that relations between them were alas far from ideally cordial and that each in his own way could sometimes be inexplicably prickly, hindering both close intellectual contact and scientific advance.



The publication of this book, which mainly consists of correspondence to and from Fisher, does much to throw light on this sensitivity, on the relationship between the three men and especially on the character of Fisher himself. With his closest friends, Fisher was always helpful and generous — perhaps his touchiness with others was a barrier put up in self-defence, or a reaction to the severe disappointment when many of his outstanding papers produced when he was young had been turned down by major scientific journals. In his letters we see the real Fisher, almost always gentle, polite, friendly and idealistic, and most willing to listen to argument. Rather than the almost impenetrable and tortuous prose of much of Fisher's scientific writings we have instead a limpid expression of his thoughts.

Two other points emerge from the correspondence printed here. The idea of evolution through selection acting on rare mutation, which from around 1935 seemed obvious common sense, and the consequent mathematical theory, had achieved this position of seeming to be the most logical and proper approach to evolution only quite recently by reason of the work of Fisher, Haldane and Hogben. And the unnecessarily strained relations between the three protagonists were largely of recent origin — a few years earlier friendship and helpfulness had prevailed.

There are occasions when a new branch of knowledge seems to be born suddenly, rather than by a process of gradual accretion. Fisher's 1918 paper "On the Correlation between Relatives on the Supposition of Mendelian Inheritance" must have been one, and the appearance in 1921 of his book *Statistical Methods for Research Workers* another. The paper on correlations between relatives covered the topic so thoroughly that not a great deal has been added to the conclusions in the 64 years which have followed. It appears that we owe the appearance of this paper to the constant encouragement of Major Leonard Darwin (Charles Darwin's son) who corresponded regularly and frequently with Fisher for 27 years. In their letters important insights emerged, some of which did not find their way into Fisher's published papers. For example, William Hamilton has attributed the inspiration of his theory of the evolution of altruism to remarks by Haldane. But in a letter to Darwin on 27 June 1929, Fisher shows that he had understood the essential point already, namely that an organism's willingness to sacrifice itself may nevertheless improve the chances of survival of the genes it carries because they will also be found in close relatives.

Just over a hundred pages of the book are occupied by the Darwin–Fisher correspondence, and approximately another hundred are taken up by extracts from letters on selection and evolution, including letters to (and sometimes from), W.C. Bond on blood groups, L.C. Dunn on dominance, E.B. Ford on selection in butterflies, J.B.S. Haldane on miscellaneous topics, J.S. Huxley on Family Allowances and S. Wright on topics in the mathematics of selection. The book also contains some other papers by Fisher which are unpublished or not readily accessible. In all, it illuminates in an interesting and informative way the development of the theory of natural selection during the years 1910–1960, both as regards Fisher's own personal contributions and his reactions to those of other pioneers. □

Cedric A. B. Smith is at the Galton Laboratory, University College London.

R.A. Fisher (right) with C.D. Darlington at a genetics conference in Stockholm, 1948.

End of blue-green algae

Sergey V. Shestakov

The Biology of Cyanobacteria.
Edited by N.G. Carr and B.A. Whitton.
Blackwell Scientific/University of California Press: 1982.
Pp.688. £42, $75.

IT IS now unarguable that phototrophic organisms, which have for over a century been called blue-green algae, belong to the prokaryotes and are thus the property of microbiologists rather than botanists. The best proof of this is the appearance of an authoritative book with the word "cyanobacteria" in its title. The term has thus been fully legalized. In the foreword, written shortly before his death, Roger Stanier succinctly defined them as: "Microorganisms that harbour within a typically prokaryotic cell, a photosynthetic apparatus closely similar in structure and function to that located within chloroplasts of phototrophic eukaryotes".

The book is a successor to *The Biology of Blue-Green Algae,* published by Blackwell Scientific and University of California Press in 1973, and clearly reflects the progress in cyanobacteriology made in the intervening decade. The contributors are all leading experts and between them provide comprehensive reviews of the morphology, physiology, biochemistry and ecology of the cyanobacteria, and (in the final chapter) of palaeomicrobiological aspects of their origin and evolution.

The role of cyanobacteria in freshwater and marine ecosystems is described in great detail, and the peculiarities of structure and function of membranes and cell wall, heterocysts and akinetes, phycobilisomes and gas vesicles are discussed in a new light. A lot of attention is also paid to photosynthesis, carbon, nitrogen and phosphate metabolism, and to motility and taxis. Particularly stimulating are the chapters on genetics and molecular evolution, in which the genome of cyanobacteria and their phylogenetic position within the prokaryotes and in relation to eukaryotes are for the first time exhaustively analysed. The genetic relatedness of cyanobacteria and plastids of eukaryotic photosynthesizers is well argued.

The book is not without its disappointments, however. Cyanoviruses, symbiotic systems and soil ecology of cyanobacteria are not included, while the omission of certain contemporary issues in applied biology — the use of cyanobacteria in agriculture and biotechnology, for example — is especially regrettable. (Cyanobacteria are promising subjects for the genetic engineer, and may in time provide the clues by which we unravel the intricacies of such fundamental processes as nitrogen fixation, membrane biogenesis and cell differentiation.) The editors have in general done an excellent job; but some of the authors, although giving an impressive show of their knowledge, have sadly failed to give pointers to the immediate research problems to be tackled in their specific areas.

But the plus points easily outweigh the minus. The book is extensively illustrated and thoroughly referenced, even including very recent data, which will make it a good source for advanced students and new research workers. And since cyanobacteria are now attracting an increasing number of scientists from a variety of backgrounds, this highly sophisticated book will certainly be appreciated not only by microbiologists, but also by biochemists, cytologists, ecologists, molecular biologists and other specialists. □

Sergey V. Shestakov is Head of and a Professor in the Department of Genetics at Moscow State University.

In colour

Colour Vision: Physiology and Psychophysics, a book stemming from the conference on the subject held in Cambridge, UK, in 1982, has recently been published by Academic Press. Editors are J.D. Mollon and L.T. Sharpe; price is £28, $49. Issues raised at the conference were discussed in a News and Views article in *Nature* **300**, 320; 1982.

Life dictionary

A new edition of E.A. Martin's *Dictionary of Life Sciences,* which first appeared in 1976, has been published by Macmillan Reference Books, London. According to the editor, revision of the *Dictionary* has taken account of advances in genetics, molecular biology, microbiology and immunology, while coverage of the more traditional aspects of biology has been reduced slightly. Price is £22.50.

Algebraic astronomy

P.K. Seidelmann

Vectorial Astrometry.
By C.A. Murray.
Adam Hilger, Bristol/Heyden, Philadelphia: 1983. Pp.353. £25, $49.

THE lack of a comprehensive yet readable text on spherical, or practical, astronomy is generally recognized. Instead, a number of good, specific-purpose texts*, and several, much older textbooks† which are still valuable reference works when wisely used, have had to suffice.

While astrophysics has changed drastically in the last century, astrometry has changed by degree. Thus, an astrophysics textbook from the last century would be wrong, but a spherical astronomy volume from the nineteenth century would only omit recent developments and lack the accuracy of current standards. This evolutionary progress in astrometry may explain the previous absence of a textbook based on vector and matrix algebra.

C.A. Murray's *Vectorial Astrometry* is not the much-needed comprehensive, readable text. Rather it attempts to apply vector and matrix algebra systematically to spherical astronomy. At the same time the International Astronomical Union reference system, time scales and constants, introduced at the beginning of 1984, are explained and used throughout the volume.

The personality and interests of Andrew Murray are accurately reflected by the strengths of the book. Photographic astrometry, relativistic astrometry, the theory of refraction, precession and nutation are well presented. For many subjects the latest developments are included and the vectorial and matrix equations are derived.

The volume would be significantly improved by good diagrams, however. The present two-dimensional, captionless line drawings add little to the clarity of the treatment. On subjects that are not associated with previous interests of the author, there is little in the way of descriptive explanation; the purpose appears to be the derivation of the necessary equations rather than communication of their reason and purpose. Several chapters contain individual sections without any apparent connection between the subjects. Also, I suggest reading the appendices first, so the notation and basis of some equations are understood.

While many new textbooks provide the cookbook formulae and methods for performing specific computations, this volume emphasizes the theory and derivation of equations and avoids the practical applications. Thus, under the title of astrometry through the atmosphere, the theory of refraction is discussed in great detail, but there is no mention of practical methods of calculating refraction.

For those who believe that astrometry has never entered the twentieth century, this is the book to change their minds. If you wish to apply vector or matrix algebra to spherical astronomy, if you need the relativistic formulation of astrometric calculations, and if you are interested in the latest developments and most accurate methods of astrometry, you will find this book to be interesting and useful. For all astrometrists, and for astronomers who must make accurate spherical astronomical computations, it will be an important reference volume. □

P.K. Seidelmann is at the US Naval Observatory, Washington DC.

ANNOUNCING

NEW FOR 1984

Pharmaceutical Medicine

The contents will include:

★ **Original papers**
- on methods used to evaluate the efficacy and safety of drugs in man
- with emphasis on the validation of these methods
- covering human pharmacology, clinical research, drug epidemiology, and safety surveillance
- and especially the application of new methods to drug testing

★ **Abstracts of methodological studies published elsewhere**
- either used already in the context of drug investigation
- or methods suitable for drug evaluation

★ **Invited reviews on topics related to pharmaceutical medicine**

★ **Editorials and Commentaries**
- offering opinions
- high-lighting problems

★ **Correspondence, Book Reviews, and Calendar**

UNIVERSITY OF READING
PROFESSORSHIP OF PHYSICS

Applications are invited for a Professorship of Physics which will become vacant on the retirement on 30 September 1984 of Professor H H Hopkins, FRS, Professor of Applied Optics.

Candidates should have experience and achievement within the field of applied and modern optics, interpreted in the broadest sense.

The appointment will be made from a date to be arranged with the successful candidate.

Further information may be obtained from the Registrar (Room 214, Whiteknights House), The University, Reading RG6 2AH. The closing date for applications is 16 March 1984. (1005)A

ST THOMAS'S HOSPITAL MEDICAL SCHOOL
(United Medical & Dental Schools)
POSTDOCTORAL POSITION IN HUMAN NEUROPHYSIOLOGY

Applications are invited for a post-doctoral position at the Sherrington School of Physiology to study the organization of central synaptic input to motoneurones in man. The position is supported by the MRC and will be available from January 1984. Knowledge of spike train analysis would be an advantage but is not essential.

For more details please contact Dr John Stephens, Sherrington School of Physiology, St Thomas's Hospital Medical School, London SE1 7EH. (1002)A

UNIVERSITY OF CAMBRIDGE
PHYSICIST/ENGINEER RESEARCH ASSISTANT

required to participate in development of new ion-beam equipment for secondary-ion mass spectrometry. Post-graduate experience and familiarity with ultra-high vacuum and electronic measuring techniques an advantage.

3 year appointment with starting salary in the range of £5,880 — £8,080 according to age and experience.

Applications, cv + names of two referees, to Dr J V P Long, Department of Earth Sciences, University of Cambridge, Downing Street, Cambridge CB2 3EQ by 13 February, 1984. (1011)A

ST GEORGE'S HOSPITAL MEDICAL SCHOOL
(University of London)
TECHNICIAN GRADE 3 OR 5

Required for a 3 year MRC study of embryonic sensory organs. Duties will include dissection of chick embryos, establishment of cell cultures, protein purification and histology. Appointment at T3 (Min £5,151 pa) or T5 (Min £6,279 pa) depending upon experience, plus £700 pa London Allowance.

Application form and further details from Establishment Officer (Quote Ref: TP), St George's Hospital Medical School, Cranmer Terrace, London SW17 0RE. Closing date 9th February. (1045)A

Rijksuniversiteit Utrecht

In the faculty of Sciences, subfaculty of Geology and Geophysics, is, in the Department Geophysics of the Solid Earth, the post of

PROFESSOR OF GEOPHYSICS (M/F)

vacant

His duties will concern:

- Teaching of subjects in geophysics of the solid earth, in compliance with the program of the department of Geophysics.
- Leading research to be carried out in agreement with the program of the Department.
- Participating in administrative and managerial tasks which are relevant to the Department.

Preference will be given to candidates with proven ability in the field of seismology.

The department of Geophysics of the Solid Earth, at present, comprises groups for Marine Geophysics, Paleomagnetism, Exploration Geophysics and Theoretical Geophysics (including Seismology).

The candidate is expected to give important and meaningful contributions to the further development of geophysics.

The salary scale is according to regulations between Dfl. 7378 — and Dfl. 9283 — per month.

Written applications, accompanied by a curriculum vitae and list of publications should be received before March, 15 1984, addressed to the Secretary of the Advisory Committee, Prof. Dr. N. J. Vlaar, Instituut voor Aardwetenschappen, Rijksuniversiteit Utrecht, Budapestlaan 4, 3584 CD Utrecht, the Netherlands under No 145.031.

Persons who wish to draw the attention of the Committee to potential candidates are invited to express their opinion in writing to the Secretary of the Committee.

(W675)

MACQUARIE UNIVERSITY
Sydney, Australia

SCHOOL OF BIOLOGICAL SCIENCES

LECTURER IN BIOLOGY
(Fixed-Term Appointment)

Applications are invited for the position of lecturer in Biology for a fixed-term of 5 years. Applicants should possess high academic qualifications and have shown capacity for research. Some university level teaching experience would be an advantage. The appointment will be made in one of three fields: biochemistry, molecular biology or immunology, but preference will be given to one or other of the following two specialised areas: (a) cell surface biology, with particular expertise in the production and use of monoclonal antibody reagents, (b) molecular and DNA sequencing. If the successful applicant were chosen from the first area, he or she would be encouraged to become involved with a group working on cell surface aspects of differentiation in simple eukaryotes such as Dictyostelium, while for the second area a person working with higher plants is preferred.

The present Chairs of Biology are held by Professors D W Cooper, G B Sharman and K L Williams.

Salary range $:A23,394 — $A30,734 pa.

Further information about the University and advice regarding the method of application should be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar, Macquarie University, North Ryde, New South Wales 2113, Australia.

Applications close on 24 February 1984. (W673)A

ICI

CORPORATE BIOSCIENCE GROUP

RESEARCH SCIENTIST

ICI's Corporate Bioscience Group has an opportunity for an enthusiastic graduate with a good Hons degree in biochemistry, microbiology or related discipline. The successful candidate will be a member of a small team applying microbiological systems to the synthesis of chemicals of interest to ICI. He or she should be able to adapt to a variety of techniques which may include fermentation, cell immobilisation, *in vitro* enzyme studies and analytical methods such as GC and HPLC. Experience in these areas would be desirable.

Please apply enclosing a full CV to Miss E. H. Lauermann, Personnel Officer, PO Box No. 11, The Heath, Runcorn, Cheshire.

Closing date — 2nd February 1984. (1022)A

ARMAUER HANSEN RESEARCH INSTITUTE (AHRI) ADDIS ABABA, ETHIOPIA
Founded and sponsored by the Norwegian and Swedish Save the Children Organizations

DIRECTOR OF AHRI

The position as Director of AHRI is vacant from January 1985. Applicants are invited to apply for a 2-3 years contract.

AHRI was set up as a collaborative project between the Norwegian and Swedish Save the Children Organizations and the University of Bergen in 1969 to undertake basic research in the immunology of leprosy. The Institute has at present 30 positions whereof 5 scientific. AHRI is situated in Addis Ababa, Ethiopia on the compound of an international training and rehabilitation centre for leprosy (ALERT) with 20 in-patient beds and a large out-patient clinic. There are Norwegian, Swedish, English, French and International Community schools in Addis Ababa, and a good furnished family house available.

The research work at AHRI is predominantly dealing with the immunology of leprosy, at present e.g. with detection of *M.leprae* antigens in tissues and fluids, mechanisms of tolerance to *M.leprae*, mechanisms of nerve damage, and the dynamics of cellular responses in natural infection.

The Institute is well equipped for research in these fields and the possibilities for scientific contacts outside the Institute are good. The Director of AHRI is responsible for the research activities and the administrative matters. The Director reports to the AHRI Board.

Qualifications for the position as Director are primarily scientific and may be based on an MD or PhD degree with research experience in a relevant field for the research profile of the Institute in at least the level of associate professor.

Administrative experience will also be taken into account. The Director shall conduct research on his/her own and supervise the other research activities at the Institute.

Further information is available on request from the AHRI Board.

Application in English, curriculum vitae and 3 references should be submitted to:
Professor Morten Harboe,
Chairman of the AHRI Board,
Institute of Immunology and Rheumatology,
Fr. Qvamsgt. 1.
Oslo 1.
Norway.
before 1st March 1984. (W663)A

CSIRO

Chief of Division
Division of Mineralogy
Floreat Park
Perth, WA Australia

Applications for the position of Chief of the Division of Mineralogy are invited from scientists with an established record of personal research achievement and leadership in an appropriate field of science. The position became vacant on October 7, 1983 following the retirement of Mr. A. J. Gaskin FTS.

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology, and Physical Sciences.

Mineralogy is one of the Divisions of the Institute of Energy and Earth Resources. Also in the Institute are the Divisions of Geomechanics, Energy Chemistry, Energy Technology, Groundwater Research, Mineral Chemistry, Mineral Engineering, Fossil Fuels, Mineral Physics and the Physical Technology Unit.

The Division of Mineralogy Headquarters is located at Floreat Park, a suburb in Perth, with a major laboratory at North Ryde in Sydney, NSW, and a small laboratory at Canberra, ACT. The Division has a total staff of 112, which includes 54 professional staff.

The work of the Division, which lies within the broad objectives of the Institute of Energy and Earth Resources, is to develop better techniques for locating new ore bodies and concepts for the delineation of prospective terrain. Basic research on ore genesis and depositional environments forms an important background to this general objective.

The Chief of the Division will be responsible to the Director of the Institute of Energy and Earth Resources for the leadership, scientific direction and integration of the research programs of the Division and will encourage promotion of active collaboration with other CSIRO Divisions, Universities, appropriate State Departments, industry representatives and other institutions conducting research in relevant areas.

The salary will not be less than $A52,780 per annum plus an expenses of office allowance of $A1,250.

Appointment to CSIRO is for an indefinite period and carries Australian Government superannuation privileges, subject to normal conditions. The position of Chief of Division is offered for a negotiable term of the order of five to seven years, with subsequent options for a further term, if mutually desired, or for a senior position in the Organization.

The Division has recently been reviewed by a committee appointed by the Executive of CSIRO and a copy of the Review Committee's Report will be made available on request. The Director of the Institute of Energy and Earth Resources would be pleased to provide further information about the position and to discuss the position with potential applicants. He would also be pleased to receive advice concerning the appointment from people with a particular interest in the position. The Director, Mr. I. E. Newnham, May be contacted by telephone in Melbourne (03) 2687202.

Applications stating full personal and professional details, and names of at least three professional referees and quoting reference number A3804 should be directed to: The Director, Institute of Energy and Earth Resources, CSIRO, 9 Queens Road, MELBOURNE VIC 3004 AUSTRALIA. Applications Close: February 24, 1984. (W666)A

THE UNIVERSITY OF MANITOBA FACULTY OF MEDICINE
has positions available as

ASSISTANT PROFESSOR

These positions are available in response to the development of a multi-disciplinary program in the area of recombinant DNA technology as applied to neurosciences or endocrinology. The successful applicant(s) will be expected to develop an independent research program utilizing recombinant DNA techniques.

Send curriculum vitae including a brief outline of future research interest to Dr. Henry G. Friesen, Professor and Head, Department of Physiology, University of Manitoba, 770 Bannatyne Avenue, Winnipeg, Manitoba R3E 0W3 Canada. (NW225)A

Faculty Position Available Immediately

University of Massachusetts Medical School

The Department of Surgery seeks a full-time research scientist to direct its Division of Surgical Research. The candidate must have the Ph.D., M.D., or equivalent degree, as well as the demonstrated ability to conduct independent research. The appointee will be expected to conduct original research, as well as to coordinate, assist and direct the research of others. Research facilities and support will be provided.

The research interests of the appointee should lie in the disciplines of Physiology, Biochemistry or other basic sciences pertinent to the field of Surgery. A joint appointment in the appropriate basic science department is anticipated.

The level of appointment and salary will be commensurate with qualifications. Applications should include a curriculum vitae and the names and addresses of three references. Applications should be forwarded to:

Dr. H. Brownell Wheeler
Professor and Chairman
Department of Surgery
Univerisity of Massachusetts Medical School
Worcester, Mass. 01605

Further information may be obtained from Dr. H. Brownell Wheeler at (617) 856-2201. The University of Massachusetts Medical School is an equal opportunity employer. (NW221)A

CHAIRPERSON

Department of Physiology

The Mount Sinai School of Medicine of the City University of New York

The Mount Sinai School of Medicine of the City University of New York invites applications and nominations for the position of Chairperson of the Department of Physiology. The medical school seeks a biomedical scientist with an outstanding research program who is committed to the educations of M.D. students, PhD students and MD-PhD students.

Please send cv and list of publications to: Dr. J. P. Green, Chairman, Search Committee, Department of Pharmacology, One Gustave L. Levy Place, New York, NY 10029. An Equal Opportunity Employer.

The Mount Sinai School of Medicine

(NW220)A

UNIVERSITY OF FORT HARE
SOUTH AFRICA
CHIEF TECHNICIAN

Applications are invited from suitably qualified persons, regardless of sex, religion, race, colour or national origin, for the post of Chief Technician in the Electron Microscope Unit.

The Unit contains an H500 TEM and S450 SEM, both equipped with fully quantitative x-ray analysers, plus the usual peripheral equipment. Prospective candidates should have suitable experience in handling biological material for TEM and SEM and material for x-ray analysis, although the latter is not a prerequisite for appointment.

The University is rurally situated some 110 km from Rhodes University in Grahamstown.

The Salary will be in the range R12,030 — R13,740 per annum. A pensionable allowance of 12% is also payable. The initial salary will be determined according to qualifications and experience. (R1.68 = £1.00 approx).

Service benefits available to staff include, under certain conditions, financial assistance with removal of personal effects and travelling expenses, service bonus, foreign allowance, group life assurance, medical and pension schemes, housing assistance, generous leave and sick leave benefits, generous assistance with university education of employees dependants.

Further information on the vacancy, and application forms can be obtained from the Staff Officer, University of Fort Hare, Private Bag X1314, ALICE, Republic of Ciskei, South Africa. Completed applications should be lodged with the University by 10th March 1984. (W669)A

UNIVERSITY OF SOUTHAMPTON
DEPARTMENT OF CHEMICAL PATHOLOGY AND HUMAN METABOLISM
RESEARCH ASSISTANT

Applications are invited for the above post which is to run for four years, to work with Dr H T Delves on the determination of lead and other trace elements in biological samples using modern atomic absorption spectrophotometric techniques.

Applicants should have a good degree in chemistry or Part II GRSC and have experience of, or interest in, analytical science.

Salary will be on the 1B scale for research assistants (£6,310 — £8,530). Applications (2 copies) with curriculum vitae and names of two referees should be sent to the Staffing Department, University of Southampton SO9 5NH. Previous candidates need not re-apply.

Further information may be obtained from Dr H T Delves, telephone 0703 777222 ext 3846. Please quote ref: 1279/R.

Closing date: 31 January 1984. (1029)A

THE UNIVERSITY OF WESTERN AUSTRALIA
Perth
CHAIR IN PHYSIOLOGY

Applications are invited for appointment to the Chair in Physiology to be vacated on the retirement of Professor W J Simmonds. There is one other Chair in the Department, a Personal Chair held by Professor E H Morgan.

Applicants must hold appropriate higher qualifications and must be able to demonstrate a substantial research background in human or mammalian physiology. The Department is strongly represented in cellular and neurophysiology and is therefore seeking applicants from other areas of physiology. However, applicants from all areas will be considered. Whilst preference will be given to medically qualified candidates, applications from persons with other appropriate qualifications will be welcome. previous experience in the teaching of Physiology to Medical and Science students at both undergraduate and graduate levels is essential.

The current salary for the appointment is $A48,997 per annum, plus a preclinical loading for medical graduates of $A4,386 per annum. Benefits include superannuation, fares to Perth for appointee and dependent family, removal allowance, study leave and long service leave, eligibility for interestate travel grants and housing loan scheme. Further information including conditions of appointment may be obtained from the Staffing Officer, University of Western Australia, or from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications in duplicate stating full personal particulars, recent photograph, qualifications, experience and the names and addresses of three referees should reach the Staffing Officer, University of Western Australia, Nedlands, Western Australia 6009, by 3rd March 1984. (W674)A

UNIVERSITY OF CALIFORNIA
Berkeley
POSTDOCTORAL RESEARCH

Applications are invited from persons having a PhD in Biochemistry or related fields for postdoctoral positions in the laboratories of Drs Bruce Ames, Lester Packer and Martyn Smith. These positions are sponsored by the National Foundation for Cancer Research. Research will be directed towards understanding the role of oxygen radicals in cancer and aging. Preference will be given to candidates with expertise in HPLC.

Please send curriculum vitae to Dr M T Smith, BEHS, School of Public Health, University of California, Berkeley, CA 94720. Telephone (415) 642-8770. The University of California is an Affirmative Action, Equal Opportunity Employer. (NW229)A

UNIVERSITY OF DUBLIN
Trinity College

LECTURESHIP IN GEOLOGY

Applications are invited for the above post in the Department of Geology at Trinity College, Dublin, tenable from 1st October, 1984.

Preference will be given to candidates with interests in structural geology or geochemistry. A commitment to field work is essential.

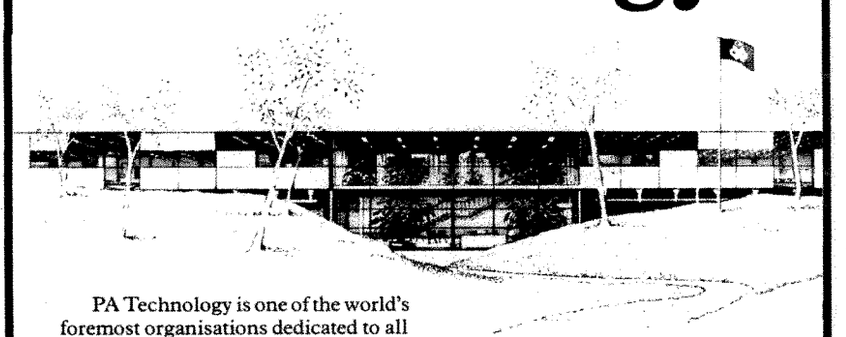
Salary Scale: IR£8,411 – £17,311 per annum.

Appointment will be made within the salary range IR£8,411 – £10,730 p.a. at a point to accord with qualifications and experience to date. Application forms and further particulars relating to this post may be obtained from:

Establishment Officer, Staff Office, Trinity College, Dublin 2. Ireland. Tel: Dublin 772941 ext 1775.

The closing date for receipt of completed applications will be 29th February, 1984. (1041)A

ST THOMAS'S HOSPITAL MEDICAL SCHOOL
(United Medical and Dental Schools)
London SE1 7EH



DEPARTMENT OF HISTOPATHOLOGY

ELECTRON MICROSCOPY UNIT JUNIOR MLSO

required in this Department, which provides research and diagnostic services in transmission and scanning electron microscopy for St Thomas's Hospital and Medical School. Previous experience an advantage. Salary on Whitley Council scale according to age, qualifications and experience.

Apply in writing, with names and addresses of two referees to Senior Chief MLSO from whom further information is available. (01-928 9292 ext 2549). (1040)A

Biotechnology

PA Technology is one of the world's foremost organisations dedicated to all aspects of new product and process development, placing emphasis on the strategic consequences of such development, and operating worldwide from laboratories in the UK, the USA, Belgium and Australia.

The continued expansion of our Cambridge Laboratory has created several new and challenging posts in our highly successful biotechnology group.

We are seeking high calibre scientists in a number of areas. In selecting appropriate candidates, emphasis will be placed on:

— proven scientific record
— creative/innovative skills
— commercial awareness
— ability to work in a multi-disciplinary environment
— good communicative skills

The posts are in:

- **genetic manipulation**
- **enzyme technology**
- **medical biosensors**
- **monoclonal antibody production**

Successful applicants for these posts will probably be educated to PhD level and subsequently have spent a number of years working towards commercially-directed goals. They will be authoritative within their own area of expertise and have a broad knowledge of commercial developments in the biotechnology area. They should have the ability to establish new project areas within our organisation and to direct these through to completion.

- **applied microbiology/biochemistry**
- **medical biosensors**

These are posts suitable for graduates which call for sound scientific ability coupled with commercial acumen. Applicants should have at least two years' experience in a commercial environment since graduating.

The salaries and other benefits for these posts will be compatible with the high quality of staff we are seeking and are unlikely to present a problem.

For further details about our company, and an application form, please write or phone our Personnel Department, PA Technology, Cambridge Laboratory, Melbourn, Royston, Herts SG8 6DP. Tel: Royston (0763) 61222.

CENTRE INTERNATIONAL DE RECHERCHES MEDICALES DE FRANCEVILLE – GABON
RECHERCHE

INGENIEUR DE LABORATOIRE RIA POUR SON LABORATOIRE D'ENDOCRINOLOGIE

Fonctions

- Supervision des dosages radioimmunologiques de routine et Organisation du Travail (Equipe de 5 techniciens)
- Mise au Point de Nouvelles Techniques.
- Participation aux Programmes de Recherched en Biologie de la reproduction.

Excellentes conditions de travail contrat debut Janvier 1984 pour 2 ans renouvelables. Conditions habituelles d'expatriation.

Candidatures àadresser à Monsieur le Directeur Général du CIRMF, 28 bd de Grenelle, 75015 Paris, avec curriculum vitae, références professionelles et prétentions. (W612)A

PUBLIC HEALTH LABORATORY SERVICE BOARD
PHLS CENTRE FOR APPLIED MICROBIOLOGY AND RESEARCH

A vacancy exists for a post doctoral molecular biologist to work jointly in the Molecular Genetics Laboratory and the Pathogenic Microbes Research Laboratory on a project to investigate the genetics of virulence and antigenicity in the bacterium *Bordetella pertussis,* the causative agent of whooping cough. This post is a fixed term contract, funded for three years by an MRC project grant, and is immediately available. The project will involve nucleic acid hybridisation, molecular cloning techniques and the use of transposon mutagenesis to study gene function. Experience in these techniques would be advantageous but not essential. Other applicants with experience in molecular biology or genetic manipulation are invited to apply and will receive favourable consideration.

The appointment will be made at the Senior Grade Microbiologist level £9,010 – £9,605 National Health Service terms and conditions will apply. Further information about this post can be obtained from Dr. C. Duggleby or Dr. A. Robinson on Idmiston (0980) 610391.

Applications, including curriculum vitae, and the names and addresses of three referees, should be sent to Mrs. Bushby, Personnel Officer, PHLS Centre for Applied Microbiology and Research, Porton Down, Salisbury, Wiltshire SP4 0JG.

Closing date: 3 February 1984. (1004)A

UNIVERSITY OF
SURREY

HEAD of the Department of Chemistry

Applications are invited for the post of Professor of Chemistry and Head of the Department.

The Department has a number of well-founded research activities with an applied orientation, and a strong commitment to the industrial year in the undergraduate course.

The successful candidate is likely to have wide experience as a chemist and to have a proven research record. Applications will be especially welcomed from candidates with a strong interest in the fields of macromolecular chemistry (including the synthesis of large molecules, and the study of their structure, function and reaction mechanisms) or the chemical effects of interfaces particularly, but not exclusively, in inorganic systems.

Further particulars are available from the Academic Registrar (LFG), University of Surrey, Guildford, Surrey GU2 5XH, or telephone Guildford 571281 ext 633. Applications giving the names and addresses of three referees, should be sent to the above by 29 February 1984 quoting reference 229/N. (999)A

UNIVERSITY OF BERGEN, NORWAY

UNIVERSITY LECTURERSHIP IN SEDIMENTOLOGY

A position as *university lecturer* is vacant at the Geological Institute (Dept. A), University of Bergen, Norway. Applicants must have an MSc, PhD or equivalent qualifications and competence in sedimentology (preferably clastic sedimentology). Experience in sedimentary mineralogy and geochemistry will be advantageous.

The vacant position is in association with the research group in sedimentology/petroleum geology which is composed, in addition to the advertised position, of a scientific staff of 5. The successful candidate must be able to take part in teaching at both undergraduate and postgraduate levels according to the requirements of the institute and follow the regulations which apply for the position. Applications from women are encouraged. Further particulars about the lectureship may be obtained from the Secretary of the Faculty of Sciences, PO Box 25, 5014 Bergen Universitet, Norway. The salary will be in the range NKr. 123.496 – NKr. 162.917.

Applications, with a complete curriculum vitae, copies of degrees and testimonials together with one set of scientific publications and a list of these in triplicate should be sent to the University of Bergen, Personnel Department, PO Box 25, 5014 Bergen – Universitet, Norway, by 20th March 1984. (W677)A

MCGILL UNIVERSITY
LADY DAVIS INSTITUTE FOR MEDICAL RESEARCH
RESEARCH IN AGING

A new unit for research in aging is being established at the Lady Davis Institute. Three positions are available immediately. These will carry appointments in the Faculty of Medicine, McGill University. One post is tenure-track, at the Associate Professor level; two are at the Assistant Professor level and may become tenure-track. It is anticipated that three more positions will be available over the next two to three years. Areas of major interest in relation to the aging process are molecular genetics, immunology and hormonal/neuropeptide changes of higher brain centers; however, other areas of research are not excluded.

Applications are invited from all; in accordance with Canadian immigration regulations applications from Canadian citizens and landed immigrants will be considered first. Review of applications will begin March 1 and will continue until suitable candidates are selected.

Send curriculum vitae, brief description of present and proposed research and names of three referees to Dr. Norman Kalant, Director, Lady Davis Institute for Medical Research, 3755 Cote St. Catherine Road, Montreal, Que. Canada H3T 1E2. (NW226)A

ZENTRUM FUER GENTECHNOLOGIE AN DER UNIVERSITAETMUENCHEN

SENIOR RESEARCH SCIENTIST ARBEITSGRUPPENLEITER

Applicants are invited for an independent research position in eucaryotic molecular biology. Candidates will be expected to develop and direct a vigorous research program in synthetic biology and/or gene structure and function. Positions will be filled for 5 years. Salary will be commensurate with experience and accomplishments.

Applications, including a curriculum, a list of publication and names of 2 references, should be sent by 29 February 1984 to Prof. E. L. Winnacker, Institut Fuer Biochemie, Karlstrae 23, D-8000 Muenchen 2. (W676)A

UNIVERSITY OF LONDON
KING'S COLLEGE LONDON
QUEEN ELIZABETH COLLEGE
CHELSEA COLLEGE

READERSHIP IN ANATOMY

The Senate invite applications for the above Readership tenable at King's College London, to be filled as soon as possible in 1984. Medical qualifications, although not essential, would be an advantage.

Applications (11 copies) should be submitted to the Academic Registrar (N) University of London, Malet Street, London WC1E 7HU, from whom further particulars should first be obtained. Closing date for receipt of applications is 22 February 1984. (1021)A

NEWNHAM COLLEGE
CAMBRIDGE

DIRECTORSHIP OF STUDIES IN MEDICINE AND COLLEGE LECTURESHIP IN A MEDICAL SCIENCE

Applications are invited from men and women for the post of Director of Studies in Medicine, to be held in conjunction with a full-time or part-time College Lectureship in one of the following subjects: Anatomy, Pathology, Pharmacology or Physiology. The successful applicant will be expected to be actively engaged in research in the Biomedical Sciences, but need not necessarily hold a medical qualification. Separate appointment as Director of Studies only may be considered for a candidate already holding a full-time post in Cambridge. A woman appointed to a College Lectureship will be elected a Fellow of the College; under the College Statutes Fellowships are open to women only.

The appointment will be for five years and may be renewable. The salary for a full-time Lectureship is on the scale of Cambridge University Assistant Lecturers and Lecturers according to age and experience. The Directorship of Studies is separately remunerated. Further particulars may be obtained from the Principal, Newnham College, Cambridge CB3 9DF, to whom applications giving particulars of qualifications and experience and the names of three referees should be sent by 15th February 1984. (1020)A

ASSOCIATE Chief of Staff for Research position available at the Portland VA Medical Center, affiliated with the Oregon Health Sciences University. Responsibilities include administration of growing multidisciplinary research program, coordinating move to new hospital under construction, and maintaining liaison with affiliated programs. Candidates should have a record of nationally recognized ongoing research, background in basic and clinical sciences, and previous administrative experience. MD's preferred. Application deadline March 1, 1984. Send letter of interest, CV and list of 3 references to Daniel E Casey, MD, Chairman, ACOS/Research Search Committee, Psychiatry Service (116A) 3710 SW US Veterans Hospital Road, PO Box 1034, Portland, OR 97207. Equal Opportunity Employer. (NW187)A

THE FLINDERS UNIVERSITY OF SOUTH AUSTRALIA
SCHOOL OF MEDICINE

POST-DOCTORAL APPOINTMENT IN ELECTROPHYSIOLOGY

Applications are invited from suitably qualified persons with post-doctoral experience in intracellular microelectrode recording from nerve cells, preferably in mammalian ganglia. The appointee will be responsible for an investigation of the actions of opiates, in relation to their addictive properties, in enteric ganglia. This NH & MRC funded position, which is under the supervision of Drs M Costa and J B Furness in the Centre for Neuroscience, is available until December 1986 in the first instance.

Salary range: $A20,164 – $A30,733 depending on number of years of post doctoral experience.

Applications, including full curriculum vitae, details of academic record and publications, research interests and the names and addresses of three referees, should be lodged, in duplicate, with the Registrar, The Flinders University of South Australia, Bedford Park, South Australia, 5042, by 30 January 1984. Late applications may be accepted. Applicants should ask their referees to forward their confidential reports to the Registrar by the closing date. (W665)A

DUBLIN INSTITUTE FOR ADVANCED STUDIES
SCHOOL OF THEORETICAL PHYSICS

Applications are invited for a

RESEARCH POST AS ASSISTANT PROFESSOR

in the School, tenable for one or two academic years commencing 1 October 1984. Salary: IR£12,572 per annum.

Appplicants should send a *curriculum vitae* and list of publications, together with the names of two referees, so as to reach the undersigned not later than 12 March 1984. No application forms are issued.

The Registrar, Dublin Institute for Advanced Studies, 10 Burlington Road, Dublin 4, Ireland. (1027)A

UNIVERSITY OF CALIFORNIA, BERKELEY

DEPARTMENT OF ASTRONOMY AND ASTROPHYSICS

ADJUNCT ASSISTANT PROFESSORSHIP

Pending final budgetary approval, the Department of Astronomy of the University of California at Berkeley expects to make one non-tenure track appointment renewable up to five years in astronomy/astrophysics at the Adjunct Assistant Professor level, which can start as early as July 1, 1984. Applicants should send a curriculum vitae, bibliography and a brief statement of research interests, and should arrange to have three letters of recommendation sent to Jonathan Arons, Chairman, Search Committee, Department of Astronomy, University of California, 601 Campbell Hall, Berkeley, CA 94720. All materials should be received by February 1, 1984.

The University of California is an Equal Opportunity, Affirmative Action Employer. (NW181)A

DRUG DISPOSITION/DRUG DELIVERY

The School of Pharmacy, University of Wisconsin-Madison has an opening on the tenure-track faculty at the Assistant Professor level in the broad area of drug delivery or drug disposition. The successful applicant will be expected to initiate an independent research program. The research may be concerned with biological transport and binding mechanisms, chemical transformations, or other basic topics related to the physiological and biochemical phenomena involved in the delivery of drugs to their sites of action; and it may make use of physicochemical, biophysical, pharmacokinetic, biochemical, immunological, or other types of quantitative investigational approaches. An emphasis on the molecular or cellular level approaches is essential. Responsibilities also include participation in pharmaceutics teaching at the undergraduate and graduate levels. A PhD in an appropriate field is required.

Please submit curriculum vitae, including names of at least three references, to Dr Kenneth A Connors, School of Pharmacy, University of Wisconsin, 425 No Charter Street, Madison, Wisconsin 53706.

The University of Wisconsin is an Equal Opportunity/Affirmative Action Employer. (NW223)A

Exciting research opportunity in West Germany
Partake studies on
EPITHELIAL AND MEMBRANE TRANSPORT

using biochemical techniques. Ideal candidate should have MD and/or PhD (Postdoc or junior faculty) and should have experience in protein chemistry and preparative organic chemistry. In addition to the researcher's salary, this federally funded position includes salary for one technician, start-up funds and an appropriate supply budget. The research laboratories are part of the Max-Planck-Institut fuer System-physiologie in Dortmund, West Germany. Starting date: March, 1984.

Please send CV and references to Dr Rolf Kinne, Director, Max-Planck-Institut fuer System-physiologie, Rheinlanddamm 201, 4600 Dortmund 1, West Germany, Deadline for application: February 29, 1984. (W672)A

WELSH NATIONAL SCHOOL OF MEDICINE
(University of Wales)

DEPARTMENT OF PHARMACOLOGY AND THERAPEUTICS

THE POST OF A GRADE III TECHNICIAN

renewable annually is available for suitable candidates in the above Department of Heath park, Cardiff. The successful applicant will be expected to assist in the organisation of a quality assessment scheme for drug measurement.

Preference will be given to candidates with experience in quality control procedures and drug assay techniques. Applicants should possess a Degree or equivalent qualification or appropriate practical experience.

Commencing salary will be dependent upon age on the Scale for University Technicians Grade III (£5,151 — £6,035).

Further particulars and application forms (quoting Ref No P8B) are available from the Registrar and Secretary, Welsh National School of Medicine, Heath Park, Cardiff CF4 4XN (Tel: No. 0222/755944 ext 2296). Closing date for application 31st January, 1984. (1015)A

CSIRO
Postdoctoral Research Fellowship
$A24,344 — $A30,038
Division of Environmental Mechanics
Canberra ACT Australia

Field: Physics of Soil Erosion by Wind and Water.

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Environmental Mechanics is a member of the Institute of Physical Sciences.

Research in the Division of Environmental Mechanics is directed primarily at gaining a better understanding of the biological and physical processes of the soil-plant-atmosphere system with particular regard to the transport of energy, water, nutrients and other materials. Facilities include laboratories for soil physics, solar radiation, fluid mechanics, micrometeorology and physiology, as well as mobile laboratories for study of the field environment. The laboratory has a large and well instrumented boundary layer wind tunnel, and computer facilities for the collection and analysis of experimental data. The Division has a micrometeorology field site located 45 km from Canberra. Divisional staff at present includes 15 research scientists (biologists, physicists and mathematicians) together with experimental and technical staff, and is usually augmented by several visiting research workers.

The Division's research is being expanded to include a study of the problems of predicting and controlling erosion in the natural and agricultural environment. Applications are invited from suitably qualified persons to undertake theoretical and experimental investigations of the mechanisms involved in the movement of soil particles by wind and water. These investigations will interlock with work done by the Division on the relationship between rainfall intensity, soil physical properties and ponding; and work on the turbulence characteristics of air flows over rough and topographically variable terrain.

Applicants should have a PhD degree or equivalent, supported by evidence of proven research ability.

A fixed term appointment of three years within the classification of Research Scientist. An applicant with an outstanding research record may be offered appointment at a higher level. Australian Government superannuation benefits are available.

Applications stating full personal and professional details, the names of at least two scientific referees, and quoting No. A0456 should be directed to:

The Chief,
CSIRO Division of Environmental Mechanics,
GPO Box 821,
CANBERRA ACT 2601. AUSTRALIA.
By February 29, 1984. (W667)A

MERRELL DOW RESEARCH INSTITUTE
STRASBOURG CENTER — FRANCE

PHARMACOLOGIST

An opportunity has arisen for an experienced pharmacologist with cardiovascular interests to work in our research center. The successful applicant will be expected to contribute to research on the mechanisms of action of calcium antagonists and on their development as therapeutic agents.

Candidates should have a PhD or equivalent degree and relevant post-doctoral experience.

The post gives the opportunity of working in a challenging research field, in very pleasant surroundings.

Salary will be commensurate with experience.

Applications and CV to Personnel Manager, Gisela Nguyen-Dinh, 16, rue d'Ankara, 67084 Strasbourg Cédex, France. (W664)A

AGRICULTURAL BIOTECHNOLOGY

Shell Development Company is seeking scientists with significant records of achievement who are interested in applying their skills to agronomic research.

Positions are available for outstanding Ph.D.-level scientists with training in one of the following:

- Agricultural Microbiology
- Plant Molecular Biology
- Plant/Invertebrate Pathology
- Plant Cell and Tissue Culture

Shell Development Company at Modesto, California offers an outstanding research environment, a reasonable cost of living, and attractive salaries and benefits. Modesto is close to the San Francisco Bay Area and the Sierra Nevada Mountains. Shell's current staff includes a strong team of innovative scientists with a record of technical accomplishment and commercial success in agrochemicals research.

Applicants should be U. S. Citizens or have permanent resident visa. Interested applicants should send a résumé, in confidence, to: Manager, Employee Relations, Shell Development Company, Biological Sciences Research Center, P.O. Box 4248, Modesto, CA 95352.

Shell Development Company

An Equal Opportunity Employer M/F

(NW227)A

SENIOR ORGANIC GEOCHEMIST

Division Head Required for Interdisciplinary Exploration Team

Woodward-Clyde Oceaneering, an expanding International Geological consulting firm based in Aberdeen, invites applications from individuals with a PhD Degree and a minimum of five years experience in Petroleum Geochemistry. Responsibilities will include developing and managing geochemical hydrocarbon exploration programmes in frontier basins, both terrestrial and marine, utilising current theories in organic geochemistry. Knowledge of a variety of instrumental methods such as GC, GC/MS, Fluorescence, Pyrolysis and Isotope Ratio/MS is desirable.

This position provides the opportunity of working with a multi-disciplinary exploration team consisting of Geologists, Geophysicists and Engineers. Résumés will be treated confidentially. Please state availability. The successful candidate would be expected to assume duties in March/April 1984.

Salary will be negotiated within the range of £15,000 to £22,500, to be commensurate with experience. Interviews will be scheduled in London and Aberdeen during the week of 30 February 1984. Reply to Box No 925 c/o Nature, 4 Little Essex Street, London WC2R 3LF.

(925)A

TEXAS A&M UNIVERSITY

DEPARTMENT OF BIOLOGY

HEAD

Applications and nominations are invited for the position of Head of the Department of Biology at Texas A&M University.

The Department of Biology, with a faculty of 38, is an administrative unit of the College of Science offering BS, MS and PhD degrees in Biology, Botany, Microbiology and Zoology.

Candidates for the position must have an earned doctorate, a distinguished record in research and teaching, and other professional accomplishments. Candidates are sought who have demonstrated leadership abilities and a commitment to developing strong academic and research programs in Biology.

Candidates should be available to assume the position by September 1, 1984. Nominations and applications, with résumés and names and telephone numbers of references, will be accepted until February 15, 1984 or until a suitable candidate is identified. Materials should be sent to: Dr C J Maxson, Associate Dean, College of Science, Texas A&M University, College Station, Texas 77843. Phone (409) 845 7361.

Texas A&M is an Equal Opportunity Affirmative Action Employer.

(NW190)A

UNIVERSITY OF LONDON

READERSHIP IN PHARMACEUTICAL CHEMISTRY AT THE SCHOOL OF PHARMACY

The Senate invite applications for the above Readership from graduates in pharmacy, physical chemistry, chemical physics, physical biochemistry or biophysics. The duties will include teaching for the B Pharm and BSc (Pharmacology and Toxicology) Honours degrees.

Current physical research in the department involves fundamental and drug-related applications of light scattering and diffusion, nmr and mass spectroscopy, electrochemistry and electrochemical methods, macromolecular chemistry, and physical approaches to drug design.

Candidates should have an established record of published research. The successful candidate will take up the position as soon as possible after 1 June 1984. Salary will be in the range £13,515 — £16,925 plus London Weighting of £1,186.

Applications (ten copies) should be submitted to the Academic Registrar (N), University of London, Malet Street, London WC1E 7HU, from whom further particulars should first be obtained. Closing date 28 February 1984. (997)A

POSTDOCTORAL POSITION available after January 1, 1984 in Genetic Sequence Analysis, to investigate problems in sequence pattern recognition and molecular evolution. Experience in Molecular biology and/or computer science required. Salary: $15,000 to $18,000 per annum. Send résumé and references to Dr T F Smith, Biophysics Laboratory, Northern Michigan University, Marquette, MI 49855. An Equal Opportunity Employer.

(NW219)A

ST MARY'S HOSPITAL MEDICAL SCHOOL

(University of London)

Norfolk Place,

London W2 1PG

DEPARTMENT OF CLINICAL PHARMACOLOGY

POST-DOCTORAL RESEARCH FELLOW (NON-CLINICAL) IN CARDIOVASCULAR PHARMACOLOGY

The appointment is for one year in the first instance, with a possible extension to a maximum of three years.

The research programme involves the investigation of drug actions on isolated human blood vessels. Applicants with previous experience in adrenergic and/or cardiovascular pharmacology will be preferred.

Salary range: £6,310 — £8,530 + £1,186 London Allowance.

Applications and names of two referees should be sent to the Assistant Secretary (Personnel) at above address no later than 3 February 1984. (998)A

QUEEN MARY COLLEGE
University of London
SCHOOL OF BIOLOGICAL SCIENCES

Applications are invited for the post of

RESEARCH ASSISTANT

for work funded by the Tropical Development and Research Institute on termite control by the inhibition of diuresis, under the supervision of Dr D E Bignell. Candidates should have a PhD, with experience in insect excretion, digestion or endocrinology and electron microscopy.

Initial appointment for 2 years from 1 February, with possible extension for a third year, with starting salary in range £8,376 — £9,716 per annum.

Please apply by letter, enclosing cv and names of 2 referees, to The Secretary, Queen Mary College, Mile End Road, London E1 4NS. (1030)A

THE UNIVERSITY OF SHEFFIELD
DEPARTMENT OF ZOOLOGY

LECTURESHIP IN ANIMAL POPULATION ECOLOGY

Applications are invited for a Lectureship in the above Department, tenable from 1 April 1984. Within the general area there are no restrictions on specific field of interest except that the applicant must be involved in a computer-dependent research programme and have an active interest in theoretical aspects of the subject. Initial salary in the range £7,190 — £8,530 a year, on a scale rising to £14,125 a year. Expected age of candidates up to about 27 years but older candidates not precluded.

Particulars from the Registrar and Secretary (Staffing), the University, Sheffield S10 2TN, to whom applications (5 copies), including the names of three referees, should be sent by 10 February 1984. Quote ref: R27/G. (1008)A

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
(University of London)
DEPARTMENT OF BIOCHEMISTRY AND CHEMISTRY

TECHNICIAN

required to assist with teaching duties and endocrine biochemistry research work. Experience in RIA or HPLC and/or cell culture is desirable. Applicants must have at least two years previous working experience.

Salary on scale £5,491 — £7,747 plus £1,042 London Allowance. 37 hour week. 35 days leave including Bank Holidays and customary days.

Further details and application forms are available from the School Office, RFHSM, Rowland Hill Street, London NW3 2PF or telephone 01-794 0500 ext 4262 quoting reference BAC/T. Closing date 3 February 1984. (1028)A

UNIVERSITY OF LEICESTER
DEPARTMENT OF MICROBIOLOGY

POST-DOCTORAL RESEARCH FELLOW

Applications are invited for a 3 year post-doctoral research position supported by the Medical Research Council. The project is to investigate the molecular basis of poliovirus neurovirulence using infectious cloned cDNAs. This investigation forms part of a larger programme concerned with the development of new prophylactic and therapeutic agents against medically important picornaviruses.

Previous experience of recombinant DNA techniques and/or of virology would be an advantage. Starting salary will be up to £8,530, depending on age and experience.

Applicants (PhD) should send a detailed curriculum vitae and the names of two referees to Dr J W Almond, University of Leicester, Department of Microbiology, University Road, Leicester LE1 7RH. (1016)A

CHURCHILL HOSPITAL
DEPARTMENT OF MEDICAL GENETICS

PRINCIPAL CYTOGENETICIST

We would like to appoint a scientist with considerable cytogenetic and theoretical experience preferably with PhD who would be able to assist in the management of all the various aspects of handling routine workloads under the guidance of the Head of the Laboratory.

Informal visits may be arranged by contacting Dr J Jonasson, Department of Medical Genetics, Churchill Hospital, Oxford.

Applications enclosing a full curriculum vitae and the names of two referees in writing to the Personnel Officer, Churchill Hospital, Headington, Oxford by 3rd February 1984. (1025)A

UNIVERSITY OF CAMBRIDGE

DEMONSTRATOR IN PLANT CYTOLOGY AND GENETICS

The appointments committee hope to be in a position to make an appointment to a University Demonstratorship in the Department of Botany as from 1 October 1984. The person appointed will be expected to teach plant cytology and genetics, and to assist in teaching an integrated cell biology or biology of organisms course. The applicant should have research interests in some aspect of plant cytology or genetics. The appointment will be in the first instance for 3 years, with a maximum tenure of 5 years. The salary is on an incremental scale rising from £7,630 to £9,425 per annum.

Applications with the names of two referees should be sent by 15 March 1984 to the Secretary of the Faculty of Biology 'A' Appointments Committee, Department of Zoology, Downing Street, Cambridge CB2 3EJ, from whom further details can be obtained. (1010)A

CSIRO
Research Scientist
(System Engineer)
$A24,344 — $A35,806
Division of Radiophysics
Epping NSW Australia

CSIRO conducts scientific and technological research in Laboratories throughout Australia and employs about 7,500 staff of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Radiophysics is a Division of the Institute of Physical Sciences.

General: The Division of Radiophysics conducts research in radiophysics and its application to community and industrial problems. The headquarters of the Division are located at Epping in Sydney, New South Wales. The Division also operates the Australian National Radioastronomy Observatory at Parkes, New South Wales. The Federal Government recently decided to fund the construction by the Division of a new radiotelescope array to be known as the Australia Telescope. The telescope will include an array of new antennas at Culgoora (near Narrabri) in NSW, a new antenna at Siding Springs (near Coonabarabran) in New South Wales and the existing 64 metre antenna at Parkes.

The appointee will be located at Epping but may be required to undertake trips to the Division's observatory.

Duties: The appointee will lead a group undertaking research into basic digital correlation techniques and design culminating in the production of a state of the art correlator for the Australia Telescope Project.

Qualifications: A PhD degree or equivalent qualifications in science or engineering and the ability to undertake independent scientific research. Broad experience in radioastronomy system design is essential. An understanding of VSLI design fabrication would be an advantage.

Tenure: Indefinite with Australian Government Superannuation benefits available.

Applications: Stating full personal and professional details, the names of at least two referees and quoting reference No A5083, should be directed to: The Chief, CSIRO Division of Radiophysics, PO Box 76, EPPING NSW 2121, AUSTRALIA. By February 17, 1984. (W668)A

UNIVERSITY OF EDINBURGH
DEPARTMENT OF PHYSICS

RESEARCH ASSOCIATE IN NEUTRON DIFFRACTION

Applications are invited for the post of research associate to take part in a programme of neutron diffraction experiments associated with the study of structural phase transitions. This project will mainly involve making very accurate high-resolution structure determinations, including anharmonic thermal motion, at various temperatures and pressures, usually with single-crystal samples. Experimental work will be done at the Institut Laue-Langevin, Grenoble, and on the new pulsed sources in the UK and USA.

The appointment, for up to three years, commences October 1984 at a salary according to age and experience, on scale 1A. Superannuation under USS. Applicants should have, or be about to obtain, a PhD.

Applications with the names of two referees and a statement of applicant's interests and career to date to Dr R J Nelmes, Department of Physics, University of Edinburgh, Mayfield Road, Edinburgh EH9 3JZ, to arrive as soon as possible. Further details on request.

Please quote reference No 5145. (1046)A

Research Professorships in Biology

The University of Calgary, Department of Biology invites applications for research professorships in its four Divisions: Botany, Cell and Microbial Biology, Ecology, and Zoology. Successful applicants will be nominated for University Research Fellowships awarded in open competition by the **Natural Sciences and Engineering Research Council**, Canada. Appointment will be at the assistant professor level. Remuneration will be based on the salary scale at The University of Calgary (1983: $29,741-$46,359).

Applicants must hold the Ph.D. degree and have at least two years postdoctoral experience. Only those who have a demonstrated ability to carry out productive and independent research of a high calibre will be considered. NSERC Fellowships are open only to Canadian citizens or permanent residents of Canada.

Qualified individuals should send their curriculum vitae, a brief description of their research objectives and the names of three referees before April 15, 1984 to:

THE UNIVERSITY OF CALGARY

The Chairman
Scholarship and Fellowship Review Committee
Department of Biology
The University of Calgary

Molecular Biology

CHIEF PROJECT ENGINEER
(c dna)

The research director of a world-wide leading pharmaceutic firm, is wanting a Chief Project engineer for his GENETIC RECOMBINATION UNIT. His main mission, within a team of biologists, shall be to build up a "c DNA EUCARYOTE" bank.

This man shall be 28 years old minimum, d.Sc., agronomic engineer, pharmacist, PHD... with previous successful experience in a laboratory of molecular biology.

Application possibilities are quite wide and this biologist will quickly see his research bear fruit.

Residence in a great French university town.

Please send your application file to Jacques TIXIER, ref. 333 N.

jacques tixier s.a.
7 rue de logelbach. 75017 paris

HAVAS CONTACT

membre de syntec

RESEARCH TECHNICIAN
required for project investigating intestinal mucous glycoprotein structure.
Salary scale £5,151 – £6,035 p.a. Application form from Assistant Secretary, Personnel Office, University of Birmingham, PO Box 363, Birmingham B15 2TT ref. 417/c/195. (1034)A

POST Doctoral Research Associate. Available immediately to study growth factors and protein kinase. Experience with handling of protein and tissue culture desirable. Send résumés and names of 3 references to: James Tam, Box 294, Rockefeller University, 1230 York Ave, New York City 10021. Equal Opportunity/Affirmation Action.
(NW183)A

UNIVERSITY COLLEGE DUBLIN
CHEMISTRY DEPARTMENT
NMR SPECTROSCOPY CENTRE

Applications are invited for a post carrying responsibility for the above unit. This centre will be an essential part of the Chemical Services Unit established by the Chemistry Department, University College Dublin with the aim of assisting Irish industry, especially with R&D. Instrumentation will comprise a JEOL GX270 SCM 90Q multinuclear spectrometer linked to a data system.

The person appointed will be responsible for the running of the centre including analysis of spectra and should have wide experience in NMR spectroscopy. Salary will be in the range: Ir£10,075 × 8 – Ir£12,675.

Applications giving a brief curriculum vitae and the names and addresses of two referees should be sent, as soon as possible, to Professor D. A. Brown, Department of Chemistry, University College, Belfield, Dublin 4, Ireland. (1003)A

MEMBRANE TRANSPORT POSTDOCTORAL AND RESEARCH ASSISTANT

positions are available immediately for individuals interested in pursuing studies on the structure and mechanism of the ion-translocating ATPases. We have recently demonstrated that the electrogenic proton-translocating ATPase in the plasma membrane of the eukaryotic microorganism, Neurospora operates via a mechanism that is quite similar to that of the Na^+/K^+ — and Ca^{2+} — translocating ATPases of animal cell origin.

Research will involve investigation of the biochemistry of this ATPase with the goal of elucidating the molecular mechanism of ion-translocating ATPases in general. Salaries are commensurate with experience.

Send curriculum vitae and names of three references to Dr Gene A Scarborough, Department of Pharmacology, School of Medicine, The University of North Carolina at Chapel Hill, Chapel Hill, NC 27514. Equal Opportunity Employer.
(NW228)A

UNIVERSITY OF TORONTO PLANT BIOLOGY

A limited term appointment (2 years with possible extension) will be made, effective July 1, 1984, at the Assistant Professor level. Applications are invited from botanists with a completed PhD and research expertise in any of: Cell Biology; Taxonomy and Evolution; Biochemistry.

The successful candidate will be required to pursue research and to teach in the undergraduate programme. Canadian immigration regulations require the University to assess applications from Canadian citizens and permanent residents of Canada before considering foreign applicants.

Applications should consist of a Curriculum Vitae, the names and addresses of three referees, and copies of graduate transcripts, submitted before March 31, 1984, to: Dr Joan Grusec, Chairman, Life Sciences Division, Scarborough Campus, University of Toronto, 1265 Military Trail, Scarborough, Ontario, Canada, M1C 1A4.
(NW222)A

Scientist
Division of Viral Products
Influenza Research

We have a position for a Post Doctoral Scientist to join a small group working on the molecular and biological aspects of antigenic variation in the influenza virus.

Candidates should have previous experience in molecular genetics of viruses and it would be advantageous to have an interest in viral immunology.

Salary is on a scale of £8,816 to £11,896 inclusive, dependent on experience, qualifications and age. The post is supported by external funds and is available initially for 3 years.

For further details please contact the Personnel Officer, NIBSC, Holly Hill, Hampstead, London NW3 6RB, tel 01-435 2232.
Informal enquiries may be made to Dr G.C. Schild. Please quote reference no. SU/VP/274.
(1049)A

Closing date for applications will be 10th February 1984.

HERIOT-WATT UNIVERSITY
DEPARTMENT OF PHYSICS

RESEARCH ASSOCIATES — SEMICONDUCTOR OPTICAL BISTABILITY

The bistability research team, under the direction of Professor S D Smith FRS, presently numbers fifteen scientists. Research objectives include studies of the nonlinearities that are the physical origin of semiconductor optical bistability, assessment of new materials for bistability in the infrared, near-infrared and visible spectral regions, investigations of bistable characteristics, and the development of novel devices. Achievement of the optically bistable switch has caused speculation of device applications ranging from fibre communication link repeater elements to optical parallel processing and optical signal computing. The group has a number of collaborative projects, both with Industry (through the Joint Optoelectronic Research Scheme) and with Universities throughout Europe (through the European Joint Optical Bistability Project).

Applications are invited from candidates with PhD experience in semiconductors/optical properties, optoelectronic devices, laser physics, or theory of optical properties of semiconductors.

Salaries will be in the range £7,190 to £11,615, according to age and experience.

Informal enquiries may be made to Dr B. S. Wherrett, Department of Physics — Tel: 031-449 5111 ext 2223.

Application forms are available from the Staff Officer, Heriot-Watt University, Chambers Street, Edinburgh EH1 1HX (please quote ref. no. 3/84). (1043)A

MRC CLINICAL RESEARCH CENTRE
(NORTHWICK PARK HOSPITAL)
WATFORD ROAD
HARROW
MIDDX. HA1 3UJ
MEDICAL RESEARCH COUNCIL

HEAD OF DIVISION OF COMMUNICABLE DISEASES

Applications are invited for the post of HEAD OF THE DIVISION OF COMMUNICABLE DISEASES at the Medical Research Council's Clinical Research Centre in association with Northwick Park Hospital.

Preference will be given to medically qualified applicants for whom an honorary consultant contract will be arranged with the North West Thames Regional Health Authority. Current activities of the division include virology, hospital infection and applied immunochemistry. There are close links with the newly-formed division of sexually transmitted diseases (Dr. D. Taylor-Robinson) and with the MRC common cold unit: Salisbury (Dr. D. A. J. Tyrrell CBE FRS).

The appointee will have overall responsibility for the research direction of the division and will be expected to carry out a personal research programme. The clinical research centre may be visited by direct appointment and prospective candidates should discuss details of the post with the director (Sir Christopher Booth).

Further particulars can be obtained from the Director's Office, Clinical Research Centre, Watford Road, Harrow, HA1 3UJ. Telephone 01-864 5311 ext 2220. (1013)A

MEDICAL RESEARCH COUNCIL
MOLECULAR HAEMATOLOGY UNIT
John Radcliffe Hospital
Headington, Oxford
NUFFIELD DEPARTMENT OF CLINICAL MEDICINE

MEDICAL LABORATORY SCIENTIFIC OFFICER

A medical laboratory scientific officer is required to assist with a project concerned with the isolation and characterization of mammalian haemoglobin genes. Knowledge and experience of current recombinant DNA techniques for analysis of gene structure would be an advantage but is not essential.

Minimum qualifications: HNC in medical laboratory sciences or degree in related subjects.

Salary on the Whitley Council scale: £5,491 — £7,747 per annum: Salary on appointment according to age and experience.

Application form and job description from: Departmental Administrator, Nuffield Dept of Clinical Medicine, Room 5801 level 5, John Radcliffe Hospital, Headington, Oxford OX3 9DU.

Closing date: 17th February 1984. (1023)A

UNIVERSITY OF LONDON

CHAIR OF VETERINARY PATHOLOGY AT THE ROYAL VETERINARY COLLEGE

The Senate invite applications for the above Chair which became vacant on the retirement of Professor Ernest Cotchin.

Candidates must possess a registrable veterinary qualification and a PhD or other higher degree. They must have a good general knowledge and understanding of morbid anatomy in the broad sense and should have experience in teaching. They should also have a specialised knowledge and active research interest in one or more aspects of the subject.

Salary within the professorial range. The current minimum is £18,461 per annum including London Allowance.

Intending applicants should obtain further particulars from the Academic Registrar (N), University of London, Malet Street, London WC1E 7HU, before submitting applications (10 copies).

Closing date for applications: 28 March 1983. (996)A

UNIVERSITY OF EDINBURGH

DEPARTMENTS OF SURGERY AND CLINICAL CHEMISTRY

RESEARCH FELLOW 1A

Required for a three-year appointment to join a team engaged in the development of new assay methods for peptide hormones in serum. The person appointed would be required to supervise and participate in the laboratory's development and clinical evaluation of assays. Applicants should have a higher degree, and experience of immunoassay methods and their application in clinical endocrinology.

Salary on the scale £7,190 — £8,975 according to age and experience, with superannuation.

Further particulars are available from the Secretary's Office, University of Edinburgh, Old College, South Bridge, Edinburgh.

Applications (4 copies) including a cv and names and addresses of two referees should be returned to the Secretary's Office not later than 7th February 1984.

Please quote reference No 5144. (1014)A

KENNEDY INSTITUTE OF RHEUMATOLOGY

Applications are invited for 2 posts in the Division of Biochemistry as part of a group investigating transfer of lysosomal enzymes between cells.

A POST-GRADUATE RESEARCH ASSISTANT

is required for a 3 year project funded by MRC to purify lysosomal enzymes and to measure their uptake into a range of cells. Experience in cell culture and enzyme purification procedures is desirable. Salary in the range IB, (£6,310 — £8,530 + £1,186 LA), according to age and experience.

A POST-DOCTORAL RESEARCH ASSISTANT

is required for a period of 18 months to complete a project funded by Action Research. This involves production of species specific monoclonal antibodies and their use to localise transferred enzymes in recipient cells. Salary in the range IA (£7,190 — £8,975 + £1,186 LA), according to age and experience.

Applications, together with the names of 2 referees should be sent to: The General Secretary, Mathilda and Terence Kennedy Institute of Rheumatology, Bute Gardens, Hammersmith, London W6 7DW. (1033)A

MEDICAL RESEARCH COUNCIL

RADIOBIOLOGY UNIT
MAMMALIAN CYTOGENETICS
CAREER SCIENTIST

Applications are invited for a career non-clinical scientific post in the Genetics Division.

The successful candidate will join a group working on the mutagenic effects of radiation and chemicals in intact mammals, and on formal mouse genetics. Applicants should have considerable experience of a range of techniques for study of meiotic and mitotic chromosomes in laboratory animals, and of the use of these techniques in studies of the induction and interpretation of numerical and structural chromosome anomalies caused by mutagenic treatment.

Salary and conditions of appointment will be according to the MRC's scales for non-clinical scientific staff. Further information may be obtained from the address below.

Applications, including a full CV, publications list, and names of two professional referees, should be sent to Personnel Officer, MRC Radiobiology Unit, Harwell, Didcot, Oxon OX11 0RD. Tel: Abingdon (0235) 834393. Closing date 17th February 1984. (1037)A

CONFERENCES and COURSES

UNIVERSITY OF SURREY
DEPARTMENT OF BIOCHEMISTRY

MSc IN TOXICOLOGY

Applications are invited for a postgraduate course leading to an MSc degree in toxicology. The course, which may be attended either full-time or part-time is organised by the Department of Biochemistry, University of Surrey, with the MRC Toxicology Unit, Carshalton; the British Industrial Biological Research Association, Carshalton and Shell Toxicology (Tunstall) Laboratory, Sittingbourne. During the course instruction is given in these collaborative laboratories as well as at other major toxicological institutions. Entrance requirements are as for a PhD and a limited number of grants from the Medical Research Council and the Inveresk Research Foundation are available for suitable candidates. On the successful completion of the course, opportunities may be available for students to register for a PhD in toxicology, and to undertake a period of research training either in one of the above named organisations or in other laboratories approved by the University as being suitable for toxicology research.

The Medical Research Council, the Royal Society and the Royal College of Pathology have identified toxicology as a priority area for research training and therefore support the encouragement of first class students from a variety of disciplines to become involved in the science of toxicology. In modern society contact with potentially toxic chemicals is increasing. Problems may arise from the use of drugs for medical purposes, from occupational exposure to industrial products or intermediates and from environmental exposure to natural or synthetic substances.

The course, which was the first of its kind in Europe, is designed to provide graduates in science, and medical and veterinary graduates, with an understanding and appreciation of the many disciplines involved in toxicology. Particular emphasis is placed on aspects related to the biochemical mechanisms of chemically induced toxicity, and the assessment of toxicological hazard in the manufacture, use and disposal of new chemical compounds, pesticides and medicines. The course provides a broad biological education and is a suitable introduction for those intending to undertake research on the interaction of chemicals with biological systems.

There are numerous interesting opportunities for scientists, educated initially in different disciplines, who have acquired additional knowledge of toxicology. These may be in industry, government regulatory bodies, or research institutes with good career prospects in both laboratory work and administration.

Further information and application forms to be returned by either 1st March, 1984, (British and EEC applicants) or 1st June 1984 (Overseas applicants), can be obtained from: Dr. R. S. Jones, Department of Biochemistry, University of Surrey, GUILDFORD. Surrey GU25XH. (840)C

INTERNATIONAL HUMAN GENETICS SUMMER COURSE

GENETICS AND MALIGNANCY
July 16-27
University of Leuven — Belgium

LECTURES and DISCUSSION in english will cover the following topics: DNA structure and function, gene regulation, post-translational modification of proteins, mutation, chromosomes, malignant growth and behaviour, RNA and DNA tumor viruses, oncogenes, plant tumors, teratoma, plasmacytoma, genetics and cytogenetics of human tumors.

LECTURERS in addition to the organizers will include: R. Berger (Paris), W. Rombouts (Leuven), Van Montagu (Gent), Van Rooy (Gent), M. Van de Putte (Leuven), A. A. Sandberg (Roswell Park, N.Y.).

The course will be suitable for predoctoral students and postdoctoral workers.

Applications should be sent to J. J. Cassiman, Center for Human Genetics, Campus Gasthuisberg, O&N, Herestraat, B-3000 Leuven, Belgium, not later than April 15, 1984. They should contain a curriculum vitae, applicants scientific background and interests and one letter of recommendation. There is no special application form. The course is limited to 50 participants. An accomodation fee of US $200 includes room and board.

The organizing Committee: J. J. Cassiman — H. Van den Berghe (Leuven) J. Leroy (Gent), E. Meulepas (Leuven). (W670)C

Immunology for Clinicians

21-25 May 1984

This course is intended to bring clinicians up-to-date with current concepts in Immunology. It will consist of 10 units (2 per day):

Introduction to the Immune system
Regulation of the Immune system
The major histocompatibility complex
Receptors on lymphocytes
Viruses and the Immune response
Tumour Immunity
Complement
Autoimmunity
Hypersensitivity and DTH
Parasitology

Contributors include:

Dr. B. Askonas
Professor J. R. Batchelor
Dr. P. Beverley
Dr. L. Borysiewicz
Dr. A. Cook
Ms A. Fielder
Professor J. H. Humphrey
Dr. G. Klaus
Dr. J. Lamb
Dr. E. Liew
Dr. J. Mertin
Professor N. A. Mitchison

FELLOWSHIPS

EMBL

European Molecular Biology Laboratory

PREDOCTORAL FELLOWSHIPS

The European Molecular Biology Laboratory is to award a limited number (6-8) of predoctoral fellowships for graduates wishing to study for a PhD at EMBL Heidelberg or its outstations at DESY, Hamburg or ILL, Grenoble. The areas of research in Heidelberg include membrane biology, cellular differentiation, analysis of the structure of membrane proteins and protein nucleic acid complexes and the structure and regulation of genes in procaryotes and eucaryotes. At the EMBL outstations the research centres on the elucidation of biological structures using either synchrotron radiation (Hamburg) or neutron beams (Grenoble).

To be eligible, candidates must hold, or anticipate receiving in 1984, a first or upper second class honours degree, a masters degree or a diplom in biological sciences, physical sciences or mathematics. Preference will be given to candidates from the member states of EMBL and EMBC namely: Austria, Belgium, Denmark, Finland, France, Federal Republic of Germany, Greece, Iceland, Ireland, Israel, Italy, Netherlands, Norway, Spain, Sweden, Switzerland, United Kingdom.

Short listed candidates will be asked to visit EMBL (travel expenses reimbursed) for an interview. Those awarded predoctoral fellowships will be expected to begin working at EMBL in September 1984. The normal duration of the fellowships will be 3 years subject to annual review.

The closing date for completed applications is February 1st 1984. Successful candidates will be notified by the end of April 1984.

Application forms and a catalogue giving further information about the research at EMBL and the groups participating in the Laboratory's predoctoral programme is available on request from Dr J. Tooze, Predoctoral Programme, EMBL, Postfach 10.2209, 6900 Heidelberg, F.R. Germany. (W511)E

DUBLIN INSTITUTE FOR ADVANCED STUDIES
SCHOOL OF THEORETICAL PHYSICS
Applications are invited for

RESEARCH SCHOLARSHIPS

Scholarships are awarded initially for a period not exceeding one year and will be renewed, subject to satisfactory performance, for a further year. The Governing Board may, for special reasons, extend the tenure of the Scholarship up to an inclusive maximum of three years. Commencing date will be 1 October 1984, and a limited number of stipends will be available. These awards are normally made at post-doctoral level.

For further particulars and Forms of Application candidates should apply immediately to The Registrar, Dublin Institute for Advanced Studies, 10 Burlington Road, Dublin 4, Ireland. Completed applications should reach the Registrar not later than 19 March 1984. (1026)E

E M B O

European Molecular Biology Organization

LONG TERM FELLOWSHIPS IN MOLECULAR BIOLOGY SPRING 1984 AWARDS

Next deadline: February 16, 1984

EMBO long term post-doctoral fellowships are awarded to promote the development of molecular biology and allied research in Europe and Israel. To be eligible a candidate must hold a doctorate degree and the exchange must involve a laboratory in Western Europe or Israel. EMBO fellowships are not, however, awarded for exchanges between laboratories within one country. Long term fellowships are awarded initially for one year, but depending on a review of progress, they may be renewed for a second year. In cases of exceptional scientific merit renewal for a third year is possible. The fellowship comprises a return travel allowance for the fellow and any dependents and a stipend and dependents' allowance.

Since the selection procedure may include an interview, candidates are requested to respect the deadline for complete applications which is February 16, 1984. Successful candidates will be notified of their awards immediately after the meeting of the selection committee, which is on April 27, 1984.

Application forms and further details may be obtained from Dr J. Tooze, Executive Secretary, European Molecular Biology Organization, Postfach 1022.40, 69 Heidelberg 1, F.R. Germany. (W531)E

THE WEIZMANN INSTITUTE OF SCIENCE REHOVOT, ISRAEL

Offers Postdoctoral Fellowships in the Life Sciences (Biology, Biochemistry, Biophysics), Chemistry (Physical, Organic, Geological and Biological), Mathematical Sciences, Physics and Science Teaching.

The fellowship provides a 12-month stipend (which is adjusted to the cost-of-living index), a relocation allowance and one-way air-fare. Fellowships which are renewed for a second year provide round-trip airfare.

Application forms and additional information may be obtained from the FEINBERG GRADUATE SCHOOL, of the WEIZMANN INSTITUTE OF SCIENCE, Rehovot 76-100, Israel.

The applications should reach the above address not later than May 15, 1984 for fellowships starting in September 1984 and not later than November 15, 1984 for fellowships starting in April 1985. (W671)E

THE ROYAL SOCIETY OF EDINBURGH RESEARCH FELLOWSHIPS

Applications are invited for post-doctoral Fellowships, tenable from 1 October 1984, at Scottish Universities, Colleges and Central Institutions.

Further details and application forms which should be completed and returned by 15 March 1984, may be obtained from the Executive Secretary, The Royal Society of Edinburgh, 22/24 George Street, Edinburgh EH2 2PQ. (1032)E

PATERSON LABORATORIES CHRISTIE HOSPITAL & HOLT RADIUM INSTITUTE MANCHESTER

DEPARTMENT OF MOLECULAR BIOLOGY

Two Cancer Research Campaign

POSTDOCTORAL RESEARCH FELLOWSHIPS

tenable for three years from 1 April 1984 are available in the new Department of Molecular Biology. The fellows will join a group investigating the molecular biology of Epstein-Barr virus with particular emphasis on the state and expression of the viral genome in EBV-associated tumour cells. Applicants should have a background in a relevant biological science and possess a keen interest in human tumour virology.

Requests for further details and applications, including the names and addresses of two referees should be sent as soon as possible to: Dr J R Arrand, Department of Molecular Biology, 2nd floor, Paterson Laboratories, Christie Hospital & Holt Radium Institute, Withington, Manchester M20 9BX, Lancs. (814)E

1984 BEIT MEDICAL FELLOWSHIP

Applications are invited for a special BEIT Medical Fellowship to conduct research which will be of potential benefit to the inhabitants of Zimbabwe, Malawi or Zambia. The appointment will be for one year held jointly between an established unit in the United Kingdom and an appropriate agency in one of the three countries where the Fellow will work. Selection will made by the Advisory Board of the BEIT Trust on the basis of the joint applications. The salary will be in the range of a Clinical/Non-Clinical Lecturer, according to the age, previous experience and qualifications of the applicant. There will be the usual university superannuation contributions and benefits. In conformity with the conditions under which the Fellowships were first established, every Fellow shall be a man or woman of any nationality whatsoever who at the date of election shall have taken a degree in any faculty in any University approved by the Trustees in the UK or in any country which is or has been since 1910 a Dominion, Protectorate or Mandated Territory of the Crown. Elections to this Fellowship will rarely be made above the age of 35 years. Applications from candidates must be received not later than 16 march 1984. Elections will take place in May 1984 and the successful applicant will begin work on 1 October 1984. Candidates must supply supporting statements for the programme from the Heads of the two Departments.

Forms of application and all information may be obtained from Miss D. Billington, Administrative Secretary, BEIT Medical Fellowships, Histopathology Dept., St Bartholomew's Hospital, London EC1A 7BE. (1044)E

FELLOWSHIPS

THE QUEEN'S UNIVERSITY OF BELFAST

Department of Pure and Applied Physics

POSTDOCTORAL ELLOWSHIP IN ATOMIC AND MOLECULAR PHYSICS

his SERC Postdoctoral Research llowship is tenable from 1st June 84 until 31st May 1987. The ccessful applicant will join an isting programme concerned ith the study of collision ocesses involving state selected omic and molecular photoions ing a technique based on photo-ectron-photoion coincidence ectroscopy.

ndidates should preferably hold PhD degree and have appropriate perimental experience. Initial lary in the range £7,191 – £7,632 r annum with USS. Closing date: th February 1984.

Department of Applied Mathematics and Theoretical Physics

EARCH ASSISTANTS

osts are available, funded by NSERC to carry out theoretical search in (1) low energy attering of electrons by heavy oms and ions where relativistic fects are important, and (2) low ergy scattering of electrons by olecules. The research will make tensive use of the University's mputers including a partmental VAX 11/750 as well the NAS 7000 at the Daresbury boratory and the GRAY-1 at the iversity of London via a depart-ntal link.

plicants must have a good nours degree, and preferably a D, in Physics of Applied athematics and research perience in the development and e of large scientific computer ogram packages. A knowledge of mic and molecular processes uld be an advantage.

ary range £7,191 – £8,532, placing depending on age and rience. Closing date: 1st rch 1984.

plications including curriculum ae and the names and addresses two referees should be sent to Personnel Officer, The Queen's iversity of Belfast, Northern and BT7 1NN. (1035)E

TDOCTORAL Fellowship avail-immediately to study the role of l experience on development of ections in the visual system of nibians. Experience in electro-ological, anatomical (light and on microscope) and/or tissue e techniques is desirable but not tial. Two-year position available 1, 1984. Send curriculum vitae names of three references to: Dr n Udin; Division of Neuro-gy, Department of Physiology; University of New York; alo, NY; 14214. The State ersity of New York at Buffalo is ffirmative Action/Equal Opport-Employer. (NW230)E

Atlas Research Fellowship

St. Cross College, Oxford University

The Rutherford Appleton Laboratory of the Science and Engineering Research Council in conjunction with St. Cross College, invite applications for a joint research fellowship. The aim of the Atlas Fellowship is to encourage studies, particularly those involving computers, in an area of research supported by the Rutherford Appleton Laboratory.

Topics include the following: study of condensed matter by scattering of neutron beams; some aspect of information technology including software engineering, IKBS, use of electron beam lithography in the fabrication of semi-conductor devices, image processing, computer aided design including electrical circuit design; finite element calculations; electro-magnetic systems; theoretical studies of the atmsophere and climate; remote sounding from space; image processing related to space astrophysics data reduction.

The successful candidate will be expected to undertake research work and have ideas on the programme he/she wishes to follow. Fellows have the rights and privileges of research fellows of St. Cross College, and will be expected to work on some aspect of the programme of the Rutherford Appleton Laboratory.

There will be access to exceptionally powerful computer facilities, and our involvement with numerous university research groups gives an opportunity for contact with others engaged on a wide range of exciting research programmes.

The fellowship will be tenable for a period of three years and may be extended up to a period not exceeding five years. The stipend will depend upon the age and experience of the candidates selected, within the broad range £9,500 to £14,800.

For details of research fellows' rights at St. Cross College and application forms, write to Recruitment Office Personnel Group, Rutherford Appleton Laboratory, Chilton, Didcot, Oxon OX11 0QX, or telephone Abingdon 0235 445435 quoting reference No: VN 201.

The closing date for applications is: 10th February 1984 (1009)E

serc Rutherford Appleton Laboratory

UNIVERSITY OF ABERDEEN

DEPARTMENT OF MICROBIOLOGY

TWO POSTDOCTORAL RESEARCH FELLOWSHIPS

Applications are invited for two postdoctoral Research Fellowships to join the group led by Professor W A Hamilton working on the role of sulphate reducing bacteria.

One post (ref Mic 1) financed by the SERC Marine Technology Directorate will be concerned with a study of corrosion processes associated with steel structures in the offshore oil industry, and will attempt to relate microbiological activities of biofilms with the electrical polarisation characterisation of naturally fouled steel surfaces.

A second post (ref Mic 2) is financed by BP Petroleum Development and is designed to strengthen basic continuous culture studies on the enzymology and physiology of growth of sulphate reducing bacteria on hydrogen.

Appointments will be from 1 March 1984 and will be for a minimum of one year at this stage.

Salary within range £7,190 to £8,530 per annum, with appropriate placing, within IA Scale for Research and Analogous Staff.

Further particulars and application forms from The Secretary. The University, Aberdeen, with whom applications (2 copies), specifying references no(s), should be lodged by 10 February 1984. (1019)E

MENTAL HEALTH FOUNDATION

FELLOWSHIPS

Applications are invited for **Mental Health Foundation Fellowships** from suitably qualified persons wishing to pursue **Full-time Research Work** bearing on problems of mental health, mental illness or mental handicap, whether in clinical psychiatry or in one of its supporting sciences.

Both Junior and Senior Fellowships are offered in the salary ranges of Junior/Senior Lecturer, Junior/Senior Registrar, according to seniority and experience, plus superannuation. However, Senior Fellowships are only awarded under exceptional circumstances, e.g., as a temporary measure prior to the Fellow taking up a permanent career post. The appointments, which are also open to candidates from overseas, will be for up to **three years** in the first instance and in exceptional circumstances may be extended to **five years.** Interviews will be held in May in London and the Fellowships will be taken up between the following July 1st and March 31st. Overseas candidates, if shortlisted, must attend for interview at their own expense. **Closing date: March 1st.**

Application forms and further information may be obtained from The Secretary, The Research Committee, Mental Health Foundation, 8 Hallam Street, London W1N 6DH. (1007)E

Fellowships cont p. 14

SEMINARS and SYMPOSIA

6th INTERNATIONAL SYMPOSIUM
on
MICROSOMES AND DRUG OXIDATIONS
5th-10th August 1984
Brighton, United Kingdom

The Symposium is organized with plenary sessions, posters and oral communications. Themes to be covered include:
1. Chemistry and physics of cytochrome P-450.
2. Cytochrome P-450 and the metabolism of endogenous substrates.
3. Molecular biological studies of cytochrome P-450.
4. Post-oxidation enzymes.
5. Cytochrome P-450; role in toxicity and carcinogenicity.
6. Drug oxidations in man.

Abstract should be submitted by February 29, 1984.

For further information and registration forms contact:
Secretariat
6th International Symposium on Microsomes and Drug Oxidations
Caroline Roney Medical Conference Organizer
100 Park Road
London NW1 4RN
United Kingdom
Telephone: 01-723 6722 (1048)M

CHROMATOGRAPHY DISCUSSION GROUP
One-day Symposium
University of Newcastle upon Tyne
28th March 1984
PYROLYSIS-GC/MS

Lectures to be given by W. J. Irwin, University of Aston; J. M. Hindmarch & J. Magee, Royal Hallamshire Hospital, Sheffield; B. B. Wheals, Metropolitan Police Forensic Science Laboratory; C. S. Gutteridge, Lord Zuckerman Research Centre, University of Reading; J. M. Bracewell, Macaulay Institute of Soil Research, Aberdeen; S. T. Jones, BP Research Centre, Sunbury; W. J. Criddle, University of Wales Institute of Science and Technology.

Information from the Executive Secretary, CDG, Trent Polytechnic, Nottingham NG1 4BU. Tel: 0602-418248. (1024)M

FELLOWSHIPS

UNIVERSITY OF YORK
DEPARTMENT OF BIOLOGY
POSTDOCTORAL RESEARCH FELLOWSHIP

A self-motivated immunologist is required to join a well-equipped group whose prime interest is the pathogenesis of relapse in chronic relapsing experimental allergic encephalomyelitis. The position, funded by the Wellcome Trust, is available for three years and would be concerned particularly with the role of soluble factors derived from immune cells in the CNS and the CSF. Applicants must be under the age of 32 and have worked continuously for the last three years in a university or hospital in the UK.

Starting salary: £7,630, with USS, within Range IA of the salary scales for Research and Analogous staff. The starting date is flexible.

Two copies of applications, with curriculum vitae and naming two referees, should be sent as soon as possible to Dr A J Suckling, Department of Biology, University of York, Heslington, York YO1 5DD, to whom informal enquiries can be made. (Tel: 0904 59861 ext 5839). Please quote reference number NA/6188. (1038)E

STUDENTSHIPS

KING'S COLLEGE LONDON

RESEARCH STUDENTSHIPS

Applications are invited now for research studentships leading to the PhD degree in Biophysics for the year beginning in October 1984. The Biophysics Laboratories, comprising the King's College Department of Biophysics and the MRC Cell Biophysics Unit, offer five main areas of research: Macromolecular studies of contractile systems; Cellular and developmental neurobiology; DNA and molecular genetics; Cell behaviour and motility; Crystallographic and computer graphics studies of biological molecules.

Applicants need a good honours degree, most likely in biochemistry, biophysics, biological sciences or molecular biology, chemistry or physics. A full list of research topics and supervisors can be obtained from Mr D M Drummie, King's College London, 26-29 Drury Lane, London WC2B 5RL, or by telephoning 01-836 8851 and asking for Mrs Crick. (971)F

STUDENTSHIPS

FOREST RESEARCH STATION PATHOLOGY BRANCH RESEARCH STUDENTSHIP

Applications are invited for a Research Studentship (for postgraduate study to PhD) on the genetics of pathogenicity and population structure in Nectria cinnabarina (Ascomycetes). Financial support (equivalent to NERC rates) is available immediately. Applicants should hold a first or upper second class honours degree in an appropriate biological subject. Preference may be given to applicants with a strong background in microbiology/mycology, plant pathology and genetics.

Applications, including a curriculum vitae citing details of University course work and names and addresses of two academic referees, should be sent to Dr C M Brasier, Pathology Branch, Forestry Commission Research Station, Farnham, Surrey GU10 4LH by 6th/13th February 1984. (1036)F

UNIVERSITY OF ABERDEEN MEDICAL ENDOWMENTS RESEARCH STUDENTSHIP

Applications are invited for a PhD Studentship for research in one of a wide range of biomedical subjects in Departments of the Faculty of Medicine. The value of the studentship is similar to those of the research councils.

Application forms and further details are obtainable from Mr A B Buckley, Clerk to the Faculty of Medicine, University Office, Regent Walk, Old Aberdeen AB9 1FX. Closing date for receipt of applications: 21 February 1984. (1042)F

UNIVERSITY OF SOUTHAMPT
LYMPHOMA RESEA
UNIT

Lymphoma Research Unit, Laboratory, General H Southampton SO9 4XY. T studentships will become ava 1 October 1984. The fields are (1) the interaction antibody and tumour cells largely at the molecular level the therapeutic application i models of human lymph phenotypic studies of lymphoma cells, including of immunoglobulin synth markers detected by mo antibodies.

Remuneration and conditions as for Research grants for PhD students.

electrofocusing resolution barrier

LKB's new Immobiline System!

Traditional electrofocusing

LKB Immobiline System

Courtesy of Dr. A. Görg et al., Technische Universität, München.

LKB's revolutionary Immobiline System smashes the resolution barrier in electrofocusing by replacing conventional carrier ampholytes with immobilized pH gradients.

Since gradient drift and conductivity gaps are eliminated, you can perform electrofocusing in pH gradients as narrow as 0.1 pH units, to obtain resolution previously considered impossible. Perfectly straight bands of focused proteins are obtained, even with high salt loads.

You can load 5—10 times more sample per run, for trace component analysis, or up to 100 mg protein on a 4 mm-thick Immobiline gel for extremely high resolution purification; there are no carrier ampholytes to remove afterwards.

Now, you can analyse peptides without using special staining techniques, and you can zoom-in on the fine detail of a 2-D map.

You can prepare and run Immobiline gels with your present Multiphor or Ultrophor system and the Multiphor Gradient Gel Kit. Discover for yourself the full capabilities of the Immobiline System by ordering your starter kit today!

PERFORMANCE ARCHITECTURE:
Data Acquisition and Control.
Multi-User Computation.
High-Performance Graphics.
All Simultaneously.

Masscomp's unique triple-bus Performance Architecture™ delivers unequalled system price/performance. With its dual-processor CPU and up to 7 megabytes ECC memory, the Masscomp MC-500 offers scientists and engineers outstanding computation power. With the addition of Masscomp-designed floating-point and array processors, throughput is even further enhanced.

The MC-500 runs a virtual memory, real-time UNIX™ operating system with Ethernet™ support. Supported languages include C, FORTRAN 77, and Pascal-2.™ The Quick-Choice™ multiple-window user interface offers menu-driven access to system functions.

Key system capabilities include:

DATA ACQUISITION AND CONTROL
- Bit-slice Data Acquisition and Control Processor
- One million 12-bit analog samples/second
- One microsecond external-even response

MULTI-USER COMPUTATION
- 32-bit CPU with 4K byte cache
- 16 megabyte virtual address space
- 7 millisecond 1024-point comple FFT

HIGH-PERFORMANCE GRAPHICS
- Independent 32-bit graphics processors
- 1024 x 800 x 2 x 1 pixel mono-chrome graphics
- 832 x 600 x 2 x 10 pixel color graphics

For more information on how the MC-500 is delivering results in industrial, university, government, and medical applications, call 1-800-451-1824.

More Than a Merger . . .

an Emerging Technology

A powerful technology is emerging. Its seeds are in olecular and cell biology, microbiology, biochemistry and mmunology. Rooted in the experience and knowledge of ese many disciplines, this new technology embraces adnces in every area of life science research.

Today, in the search for a fuller understanding of the echanisms of life, researchers are using tools and methods veloped in many areas of science, lessons learned and oven through years - sometimes decades - of experience. hese time-tested lessons form the core of an evolving chnology that will live through many generations, proding answers that otherwise would have been out of reach.

As this integrated technology takes shape, a new company, lidly based in experience, is emerging to serve it:

Life Technologies, Inc. At the company's GIBCO/BRL Division, we bring to the life scientist years of expertise in our respective fields, GIBCO in cell and tissue culture and microbiology, BRL in molecular biology. Together, we provide the firm, fertile ground on which science can grow: the most comprehensive selection of life science research products available.

To learn more about GIBCO/BRL and how we are helping a powerful new technology grow, ask for a copy of the booklet, "GIBCO/BRL: Products for an emerging technology."

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

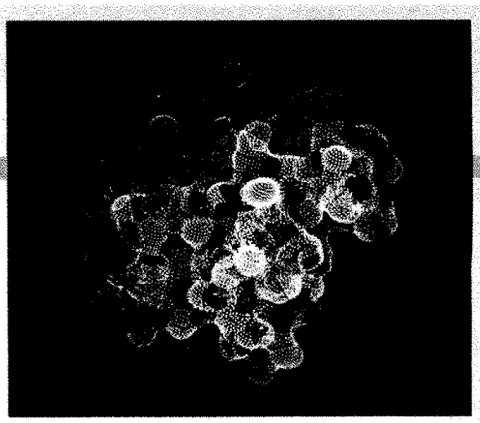
Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.



References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963–65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

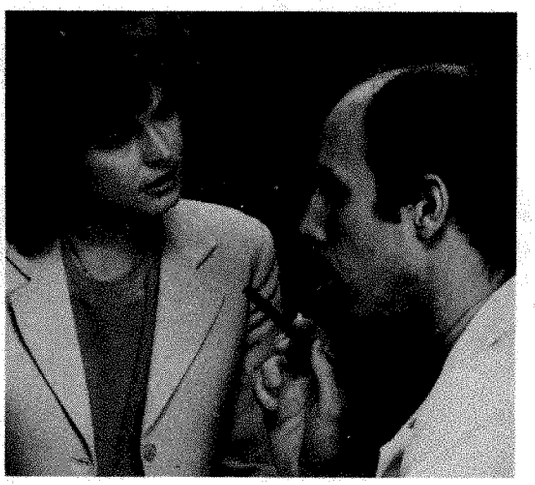
Separation of 16S and 23S rRNAs (E. coli) by HPLC on TSKgel Phenyl-5PW.

Conditions
Sample loading: 0.05 mg in 0.1 ml
Elution: 60 min linear gradient of decreasing ammonium sulfate concentration from 2 M to 0 in 0.1 M phosphate buffer (pH 7.0)
Flow rate: 0.5 ml/min
Temperature: ambient
Detection: UV absorbance at 260 nm

Circle No.20 on Reader Service Card.

Fast, sharp protein separations with high activity retained!

If you've been using a reverse phase column to separate proteins and enzymes, you may have noticed a substantial loss of activity in the sample after analysis. The separation is good, but there's low recovery of activity because the organic solvents required for sample elution often cause proteins or enzymes to unfold and denature.



That problem is overcome with the new Bio-Gel® TSK Phenyl 5PW HPLC column for hydrophobic chromatography. It requires only a **salt gradient** for elution. For example, 5 enzymes analyzed on this hydrophobic column retained at least 80% of their original activity. As you can see at left, this new alternative for HPLC separation of proteins and enzymes is fast—and just as easy and reliable—as reverse phase. Give it a try!

As always, Bio-Rad is prepared to assist you in plotting an effective strategy for your protein separations, using a growing number of techniques. Give our applications staff a call at (800) 4 BIO-RAD, or contact us at:

Sometimes a good idea begins with a product or service you didn't know about. That's where our technical representatives can help.

There's always a possibility that something you're doing could be accomplished faster, or better, or more efficiently if you had the needed information.

Often enough your NEN representative has that information—whether it be a new method, a better product, or one of NEN's extra services.

Just ask. The answer will come from solid training and experience. More detailed technical answers are quickly available, too. Our representative will see that the question is handled by the most appropriate of several sources at NEN, such as our Technical Services Group, who specialize in customer assistance.

But first talk with the person who represents it all. A good idea may be only a conversation away.

Separation power

Preparative fractionation of a 10 component mixture of proteins in 15 minutes is typical of the performance obtained with the FPLC System from Pharmacia Fine Chemicals.

High performance preparative and analytical chromatography of enzymes, monoclonal antibodies, synthetic polynucleotides and other biopolymers demands an uncompromising approach.

The FPLC System is not a compromise. New media and methodologies have been developed specifically to give the highest resolution of complex biological samples with high yields and separation times of 30 minutes or less.

Electrophoretically pure, native enzymes are typically purified from a crude tissue extract in one or two chromatography steps with a total separation time of 30–40 minutes and an overall yield of enzyme activity of 80%.

Other highly purified proteins, peptides and oligonucleotides are equally easy to obtain even in the presence of urea, non-ionic detergents or organic solvents.

The following list represents a small selection of the substances which have already been studied using the FPLC System.

Bacitracin	Alcohol dehydrogenase isoenzymes
Monoclonal antibodies	Glucose 6-phosphate dehydrogenase
Serum proteins	NADP
Urine proteins	Snake venoms
Transferrins	Bee venoms
Haemoglobins	5'-nucleoside phosphates
Synthetic oligonucleotides	Pollen extracts
Viral proteins	L-amino oxidase isoenzymes
Membrane proteins	Ovalbumin
Lactate dehydrogenase	Pyridoxalated haemoglobins
Cellulase	Gc-globulin
Tryptic peptides	Yeast proteins
Haemoglobin chains	Citrate synthetase
Insulins	Placental homogenate
Triose phosphate isomerase	2,4-dienoyl-CoA reductase

Find out how the separation power of the FPLC System can solve the separation problems in your laboratory by contacting your local representative of Pharmacia Fine Chemicals.

BIOTECHNOLOGY RESEARCH OPPORTUNITIES

THE BIOTECHNOLOGY RESEARCH INSTITUTE OF THE NATIONAL RESEARCH COUNCIL OF CANADA OFFERS A CHALLENGING AND INTELLECTUALLY STIMULATING ENVIRONMENT, ACCESS TO WORLD CLASS FACILITIES, EQUIPMENT AND EXPERTISE, AND THE INTANGIBLE BENEFITS OF A GREATER MEASURE OF INTELLECTUAL FREEDOM THAT CAN BE FOUND IN MOST OTHER RESEARCH INSTITUTIONS.

The National Research Council is establishing a new biotechnology research institute in Montreal, Canada. This new research institute will emphasize the industrial applications of biological sciences and focus on the development of new processes and products. It will foster mission-oriented research and technology transfer to industry and promote communication and collaboration amongst industrial, university, federal and provincial government laboratories.

The main areas of research will include

- **Fermentation and biochemical and process engineering**
- **Genetic engineering**
- **Cell fusion**
- **Enzyme technology.**

A major large scale fermentation facility will allow pilot scale experimentation with new fermentation methods and economic evaluation. The R & D will focus on agro-food, energy, pharmaceuticals, health care and forestry.

RESEARCH SCIENTISTS

The Biotechnology Research Institute needs researchers in the following disciplines: microbiology, biochemistry, molecular biology, enzymology, microbial physiology, genetics, cell biology, immunology, protein and nucleic acid chemistry, biochemical engineering, process and systems engineering. Applicants should have experience in the main areas of research mentioned above.

QUALIFICATIONS

Candidates should have at least 2 years relevant post-doctoral research experience. Many of the positions are at the level of section leaders and project leaders and require additional in depth knowledge of the subject area and several years of research experience.

LOCATION

The Biotechnology Research Institute will be located in downtown Montreal in a new $60 million, 18,000 m^2 complex. It will employ 220 people and will host up to 80 researchers from industries, universities and other research organizations. It will have an annual budget of $35 million.

LANGUAGES

Both English and French will be working languages at the new Institute.

BENEFITS are fully competitive and SALARY will be commensurate with qualifications and experience.

PLEASE SEND DETAILED CURRICULUM VITAE IN CONFIDENCE TO:

The polyvalent

Wild M3 Stereomicroscopes
... those with the comprehensive accessories.

High-quality optics, high operator comfort and its comprehensive modular system mark the Wild M3 stereomicroscope as the universal routine instrument for the three-dimensional observation of small objects in the laboratory, in the factory and in schools and universities.
The standard version of the Wild M3 stereomicroscope has a three-lens main objective and 10× wide-field eyepieces. Even in this combination, the three-step magnification changer shows the object as required at a magnification of 6.4×, 16× or 40×. Interchangeable eyepieces and supplementary front lenses are available for extending the magnification range. These permit a magnification from 1.5× to 160×. New inclined tubes at various angles provide the operator with comfortable, fatigue-free viewing in practically any working position of the stereomicroscope and in any posture. Interchangeable stands, lighting units and accessory equipment such as the MPS photomicrography-system, coaxial incident-light housing, drawing tube, double-iris diaphragm etc can be used according to the task in question. The Wild M3 thus becomes a universal instrument capable of performing any task.

Biomembrane Structure and Function

Edited by
DENNIS CHAPMAN
Professor of Biophysical Chemistry
Royal Free Hospital
School of Medicine, London

Volume 4 in the TOPICS IN MOLECULAR AND STRUCTURAL BIOLOGY Series
Series editors:
Professor Watson Fuller, Dr Stephen Neidle and Professor Tony Atkinson

The application of physical techniques – such as X-ray diffraction and Raman spectroscopy – has revolutionised much of our thinking on the structure and function of membranes. In this important new study, contributors of international standing review a topical selection of approaches to the elucidation of **biomembrane structure and function.** The emphasis, throughout, is on the in-depth analysis of recent experimental work.

Published January 1984 Price £50.00 432pp
ISBN 0 333 31869 2

Contents

Calorimetric studies of model and natural biomembranes – *Diana Bach*, The Weizman Institute of Science, Israel; X-ray diffraction and electron microscope studies of the molecular structure of biological membranes – *Lee Makowski and Jade Li*, Columbia University, USA; Raman spectroscopy of lipids and biomembranes – *Surendra P. Verma and Donald F.H. Wallach*, Tufts-New England Medical Centre, USA; Infrared spectroscopic studies of model and natural biomembranes – *Ralph L. Arney*, Occidental College, USA and *Dennis Chapman*; Rotational and lateral diffusion of membrane proteins as determined by laser techniques – *Winfried Hoffman*, NUKEM GmbH, E.Germany, and *Colin J. European research collaboration

The British will not be pulling out of the molecular biology laboratory at Heidelberg, but Europe needs urgently to explore ways of collaboration in research other than international laboratories.

THE British, who have earned themselves the unenviable reputation of not being reconciled to the notion that Britain is a part of Europe, have been making heavy weather in the past few years over their continued membership of the European Molecular Biology Laboratory, the international laboratory at Heidelberg in West Germany which is, confusingly, an offshoot of the European Molecular Biology Organization but constitutionally separate therefrom. The difficulties are several. When the foundation of a collaborative laboratory was first canvassed more than a decade ago, largely on the grounds that there was a need for an institution that would enliven European molecular biology as CERN at Geneva had enlivened European high-energy physics, the British Medical Research Council was one of the chief sceptics. In the pragmatic British tradition, the council argued that the analogy with CERN could be misleading, for molecular biology does not depend on the construction of huge central facilities, and that the mere existence of a central laboratory, by attracting bright people, might serve in fact to weaken national efforts in this important field.

In the event, the council's misgivings were stilled by political considerations. Ten countries (including Switzerland and Israel) signed a treaty setting up the laboratory in May 1973, and the Medical Research Council has since been the channel through which the annual British contribution to the laboratory is paid. But in that role, the council seems never to have exorcised its original doubts. The council's latest formal inquiry into the value of the work done at Heidelberg (see *Nature* 19 January, p.203) is the third occasion in ten years on which the council has thought it appropriate solemnly to appraise the value of the laboratory's scientific programme, although on this occasion it was on formal instructions from the Advisory Board on the Research Councils that continued membership of the laboratory was reviewed.

British blowing hot and cold in this way has had a predictably undermining effect at Heidelberg and among other members of the laboratory. It seems to have been widely understood that if the British chose to withdraw from the laboratory, others would follow. It has been especially disconcerting for the new director of the laboratory, Dr Lennart Philipson, that one of his chief sources of financial support (the British contribution to the laboratory is now nearly 17 per cent of the total) should be put in hazard within a few months of his appointment. Understandably, if wrongly, there have been complaints that the British were content with continuing membership only so long as a British national (Sir John Kendrew) was the director of the laboratory, and that they have seized on his departure (half-way through 1982) as the occasion for pulling out.

Moratorium

These are some of the reasons why the report of the committee of inquiry, now unexpectedly published, is so warmly to be welcomed. Its recommendation, that there should be a once and for all decision (to belong or to pull out) and then a moratorium on further introspection about membership of the laboratory, has been accepted by the research council. It is unthinkable that the Advisory Board on the Research Councils will not follow suit when it considers the matter this week.

So has the time come when people in Heidelberg can relax? Not quite. The latest British inquiry has been chiefly concerned with the laboratory's record and with its programme for the years ahead. Its report acknowledges that the laboratory has provided distinctive facilities at its two outstations (neutron diffraction at Grenoble, synchrotron radiation at Hamburg), that some of the groups at the Heidelberg laboratory are working in fields which are comparatively neglected in Britain, that many of these projects offer the chance that collaboration will yield an effort greater than the sum of its parts and that there are, indeed, opportunities for creating central pools of expertise unlikely to be replicated in the laboratories of member states. The committee of inquiry also considered the relatively high cost of the Heidelberg laboratory and offered its advice that the extra price is worth paying for the sake of the benefits of collaboration. But the inquiry has not taken up the more important question for the future of European collaboration, that of the utility of the Heidelberg as a model for collaboration in other fields.

Scepticism

The truth is that some of the original scepticism about the need for a central laboratory can still be justified. Molecular biology is not, after all, high-energy physics and the case for the Heidelberg laboratory differs in important ways from that for CERN. That, at least, is the present position, although the founders of CERN were diligent advocates of the view that central facilities at Geneva should not be regarded as a substitute for national accelerators but, rather, as a spur to member states to build big facilities of their own. That doctrine of calculated extravagance has now mercifully been dropped and CERN's justification, for the time being, is that it has, or is building machines that no member state could afford. Its worry is (or should be) that even collaboration on a European scale may be insufficient to meet the cost of the next generation of particle accelerators and that the building of large accelerators may not even be the best way of stimulating high-energy physics (see *Nature* 1 December, p.421).

The case for the Heidelberg laboratory, originally cast in similar language, is now recognized to be intrinsically different. Although there are facilities not to be found elsewhere in Europe, their provision does not hang on the existence of a central laboratory, whose justification then becomes its capacity to attract distinctive people and problems. The unanswered question is whether the same benefits might be accomplished by other means, perhaps at less cost. If, for example, there were a grant-making body operating on a European scale in the support of molecular biology, the chances are that its funds would go on the support of projects not very different from those being assembled at Heidelberg. Similarly, if national research councils were more ready than they are at present to spend money on collaborative projects, and if their governments would let them follow such an enlightened policy, much the same might be accomplished. Collaboration along lines like these could, in the long run, be cheaper, more flexible and more productive. So the case for central laboratories on a European scale is largely psychological — they entail a visible commitment by member states which cannot easily be shuffled off.

There are several practical lessons to be drawn from this argument. On the Heidelberg laboratory, the British institutions which have found it impossible to bury their doubts about the wisdom of collaboration should do what the latest inquiry

0028-0836/84/040303-01$01.00

© 1984 Macmillan Journals Ltd

recommends — pay up and do what they can to make a success of the venture. And because the venture implies a commitment not just by the Medical Research Council but by the British government, steps should be taken to see that the funds available for supporting academic research in the United Kingdom do not fluctuate with each variation of the international value of sterling or the relative economic growth of the partners in these collaborations. But none of this should be taken as a sign that European collaboration (of which there is too little) should always be organized around central laboratories. Indeed, there is the strongest case for deliberate experiments in the support of European research from central funds along the lines on which research councils function nationally. The European Molecular Biology Organization, which has won a high reputation in its administration of fellowships and training programmes, is ironically the most obvious vehicle for such an experiment. Is it outrageous to suggest that when the issue of the laboratory is settled, national research councils should bite harder on the bullet and set aside further modest funds for supporting less formal kinds of collaboration? □

Breaking all the rules

The US accuses the Soviet Union of violating arms agreements, but is breaking other rules.

THOSE who worry about the growing tension between the superpowers should remember that one of the earliest and most successful arms control agreements ever negotiated by the United States is already 167 years old. That agreement was not, of course, with the Soviet Union but with Great Britain. The Rush-Bagot agreement which, in 1817, demilitarized the Great Lakes is still regarded by historians as an outstanding instance of hostile powers entering into sensible arrangements to reduce the military friction between them. Yet for the first hundred years of its life, the treaty was the subject of heated accusations by both sides. It is conceded that its technical provisions have been violated countless times.

The US Congress would do well to keep in mind Rush-Bagot when it ponders the report it has now received from the Reagan Administration alleging that the Soviet Union is guilty of several violations of the fragile arms control regime now in place. Regrettable as they are, technical violations need not unmake a useful treaty unless the signatories choose to let them. That is why it is unfortunate that at least some members of the Reagan Administration have created the impression that they would like the still unpublished report to destroy what remains of American confidence in the trustworthiness of the Soviet Union, perhaps even to undermine the notion of arms control as such.

Why else should the administration have chosen to raise a public stink about the alleged violations before exhausting the opportunities that exist in the private Standing Consultative Commission (SCC) set up under Salt I and Salt II expressly to deal with problems of this kind? SCC has already proved itself a successful (but slow) mechanism. Between 1973 and 1977, discussions in SCC persuaded the United States that silos being constructed in the Soviet Union were indeed intended to house launch-control facilities and not new missiles. And in 1975, when radioactive material was vented into the atmosphere after a Soviet nuclear test in violation of the 1963 Limited Test Ban Treaty, private bilateral talks persuaded the Carter Administration that the technical violation had not undermined the value of that agreement.

The decision to complain in public would be more understandable if the administration had clear proof of the alleged violations, and if they were of serious military significance. Yet the United States concedes that only two of the seven violations have been confirmed to its own satisfaction and that neither of those — the alleged use of chemical and biological weapons in Afghanistan and a breach of the 1975 agreement on notification of military manoeuvres in Europe — is part of the bilateral nuclear agreements between the superpowers. The other allegations are more tentative. In some cases, such as the allegation that the Soviets have tested above the 150 kiloton threshold set by the unratified Threshold Test Ban Treaty, the technical evidence is ambiguous. In others, like the encryption of telemetry during missile tests, the superpowers differ over the legal interpretation of the Salt II agreement.

Why, then, has the administration chosen this moment to raise public questions about the value of the treaties it has signed with the Soviet Union? One plausible though perhaps uncharitable explanation is that the administration is preparing public opinion for an abrogation of the Anti-Ballistic Missile (ABM) Treaty so that it can proceed more quickly with development of the "star wars" missile defence system proposed by President Reagan last March. There are signs enough for the congenitally suspicious that the President has decided to give the star wars plan his blessing. To the Soviet Union, for example, last week's first test by the United States of an antisatellite missile (see page 306) and the President's announcement (expected this week in the State of the Union speech) that the government has approved plans for a space station, are bound to look threatening.

A slightly more charitable explanation of the administration's behaviour is that its report on Soviet treaty violations is simply another unsuccessful attempt to paper over its own political troubles. It is an open secret that the administration is divided between those who favour new arms control measures and those who want to break out of the existing regime so that the United States can recover its dominant position in strategic weapons. Complaints in public on the basis of a still-secret document may have been a convenient compromise between the two factions. The effect, however, will be to make the Soviet Union even more reluctant than it already is to answer the serious charges against it. □

West German reform

The Bonn government seems bent on carrying reform to the universities, urgently in need of it.

LEGEND has it that the student prince was almost always penniless but invariably free — free to move from one university to another, to let his inclinations guide his pursuit of knowledge or even, if that seemed more appropriate, the pursuit of other goals. In the hard decades after the Second World War, the species has become almost extinct. Now, only vestiges of the old behaviour-pattern are to be seen. Italian universities have no effective mechanism except discomfort for turning away students whom they cannot hope to teach. In France, in spite of the troubles of 1968 which filled the streets of Paris with would-be student princes, the government seems cleverly to have managed to keep the worst excesses of the old system in check, helped no doubt by economic reality of the kind that touches students. Only in West Germany have the old ways been substantially unchanged, with the result that some universities (the University of Munich, for example) are unmanagably large while others, some of the newer creations in *Nordrhein-Westfallen,* are crying out for students. And the capacity of universities to manage their affairs efficiently has been further undermined by the basic law that distributes decision-making to statutory committees able, if so inclined, to exercise the rights but not the responsibilities of power.

Against this background, the new proposals for reform now in the mill at Bonn are much more radical (and welcome) than they may seem at first sight. The idea that students should be guided to the places where they can be taught is not illiberal (as some will make out), it does make sense that students should not remain students indefinitely, it is high time that some power of decision should be returned to those who are blamed if things go wrong, and it is especially welcome that there should be a scheme for keeping people in the academic system for long enough to tell whether they will be able to find permanent places for themselves. The dangers now lie not so much in Bonn but with the backwoodsmen, the politicians in the *Länder* governments who do not see the need for reform and with the would-be student-princes. It will be interesting to see how many are left.□

US nuclear power

Cancellations promise bleak year ahead

Washington

THE new year has brought a new wave of trouble for the US nuclear power industry. Five nuclear power plants now under construction have either been cancelled or have encountered licensing problems in just the last few weeks, chiefly as a result of rising costs and newly discovered safety violations. And a report from the Energy Information Administration (EIA)* has found that average construction time for a new reactor has reached 12 years — more than twice the time it took to build a reactor in the early 1970s. Three-quarters of the plants completed in the past decade or nearing completion now have cost more than twice the original estimate. One in ten of them have cost more than seven times the original estimate.

These escalating costs, together with the failure of electricity demand to keep up with the utilities' projections, have played a large part in the recent cancellations. Last week, the Public Service Company of Indiana announced that it was abandoning the Marble Hill plant on which it has already spent $2,500 million. The River Bend plant No.2 in Louisiana was recently cancelled as well, and the two-reactor Midland plant in Michigan is facing an uncertain future, with its current estimated cost at more than ten times the original figure of $300 million.

Safety violations have aggravated economic difficulties in some other recent cases. On 13 January, the Nuclear Regulatory Commission's safety and licensing board unconditionally denied an operating permit to the Byron plant in Illinois, saying it had "no confidence" in the quality assurance programme of key contractors. Although the board did not point to specific safety deficiencies, it said that the quality assurance was so poor that there was no way to know for sure. According to the Nuclear Regulatory Commission press office, the board, in its 400-page report, charged that Systems Control Corporation, which supplied safety-related equipment, had actually run a "fraudulent and ineffective" quality assurance programme and is being investigated by the Department of Justice.

Spokesmen for the utility said the problems were only in the documentation of the quality assurance efforts, not in the work itself. They also said that the utility was losing $1 million a day as a result of the delay.

Safety troubles with Cincinnati Gas and Electric's Zimmer plant led to an unusual decision over the weekend at that troubled plant, which has stood half-finished since November 1982 when mounting quality assurance failings prompted the Nuclear Regulatory Commission to order a halt in construction. The utility decided that rather than spend an additional $1,000 to $2,000 million to complete the nuclear plant, they would convert the station to a coal-burning facility. The utility had already spent $1,700 million.

A spokesman for the Atomic Industrial Forum said the cancellations were all primarily due to the low growth in electricity demand. He said that "nuclear is a natural target" because of the large capacity of nuclear plants and their high initial capital costs.

The cancellations of half-completed nuclear plants are already sparking heated confrontations over who is to bear the construction costs — stockholders or ratepayers. The decisions in each case will ultimately be made by the state regulatory commissions which have different rules and have come down on different sides of the issue.

Stephen Budiansky

*"1983 Survey of Nuclear Power Plant Construction Costs", DOE/EIA-0439(83).

West German universities

End of old order in sight?

A RADICAL reform of West German education is in the air. Professorial powers will be increased and advance beyond the basic degree will be made more difficult if recommendations made by a commission appointed by the West German Minister of Education are accepted.

The commission's mandate was to examine the working of the 1976 University Law (*Hochschulrahmengesetz*) framed in reaction to the student unrest of the late 1960s. This shifted the balance of power from the professors (the *Ordinarienherrschaft*) to a wider group. Decision-making committees of the universities now comprise representatives including students, administrators, scientists and non-scientists, as well as professors.

The commission finds, in agreement with the *Wissenschaftsrat* and the Conference of West German Rectors, that over-diligent application of the principle of group responsibility has led to the hardening of conflicting interests, inefficiency and a mushrooming bureaucracy.

The commission wants to see the professorial and faculty role strengthened at all levels. However, the number of faculties should be limited to fifteen, and the heads of faculties (*Decane*) represented in the senate. It does not, however, agree with the rectors that the professorial complement in the senate should be increased. At present, university rectors are elected by the professors in universities of six *Länder*. The commission favours this system as against appointment by the president.

Subject to restrictions on admissions to popular faculties (*numerus clausus*) such as medicine, the school-leaving *Abitur* remains a general passport to university education and student careers have traditionally been long even with rising student numbers. The report now recommends that length of study should be controlled and academic criteria strictly applied to courses beyond the basic level.

Many bureaucratic barriers have arisen in the application of private sources of finance in university research. All such support now requires special permission and must be channelled through the university administration. The present government favours closer links between industry and the universities and will therefore agree with the recommendation that restrictions on this source of money be lifted and also that researchers be given freedom to appoint their own staffs.

The report also recommends the redesigning of the academic echelons. The present two highest levels of C3 and C4 will be amalgamated, perhaps to provide a larger pool of professional expertise. The lower C2 grade and general all-purpose university assistant would vanish, to be replaced by a class of scientific assistants who would be in the process of qualifying.

Those obtaining the *Habilitation*, the formal German professorial qualification, would be guaranteed a four-year post as an assistant, giving them time to receive the necessary invitation to a full professorship and at the same time maintaining a reserve pool of available talent.

The report has been a long time in gestation. It reflects the opinion now widely held among West German academics that the reforms of the 1970s, which diffused power widely among statutory university committees and which further strengthened the legal rights of students and junior members of teaching staffs, failed to tackle the outstanding problems of excessive demand for places in some universities and the difficulty of placing young people in any but the most demeaning academically related posts.

The problems encountered in some *Länder* of making full use of newly built universities have helped to win approval for the new proposals in the *Wissenschaftsrat*, the constitutionally unique body representing the federal and *Länder* governments which has been for the past thirty years the most powerful arbiter of policy on higher education.

The report will be the basis for discussion from which a new university law will emerge.

First US test of airborne system

Washington

MORE than a year of lobbying by prominent scientists failed to prevent the US Air Force from conducting its first test-firing last Saturday of a new antisatellite weapon (ASAT) that can be launched from underneath the wing of an ordinary F15 fighter aircraft. The test, in which the missile was fired into space but not at a target, was immediately denounced as the prelude to a dangerous new phase in the arms race with the Soviet Union.

Development of the new weapon has been justified by the Department of Defense on the grounds that the Soviet Union is already believed to possess an operational antisatellite system. But critics complain that the American air-launched system is far more sophisticated than the Soviet system and, because of its small size, will make verification of a treaty banning such weapons virtually impossible.

The Soviet Union is believed to have conducted some 20 tests of its own main ASAT system, in which an explosive interceptor is launched from the ground by a variant of the SS-9 Scarp rocket. Last March, the Pentagon claimed that the Soviet Union would be able to launch the prototype of a space-based laser weapon some time after the mid-1980s and that an operational system capable of destroying satellites within a few thousand kilometres could be completed by the end of the century.

Unlike the existing Soviet system, the American weapon tested last week is launched in flight by an F15 aircraft and consists of a miniature non-explosive homing vehicle carried into space by a two-stage rocket. The vehicle would locate its target with infrared sensors and destroy it by collision. Congress has told the Air Force not to test the new weapon against target satellites until President Reagan provides a report on the administration's efforts to curb an arms race in space.

The administration is not expected to face any substantial difficulty in persuading Congress that the tests should go ahead, however. In recent months the Pentagon has been stressing the rapid strides the Soviet Union is believed to be making in space weapons, and a report last week in *Aviation Week and Space Technology* says the Central Intelligence Agency (CIA) believes the Soviet Union is developing a space-based defence system that could destroy American ballistic missiles launched against the Soviet Union.

At present there are no international treaties forbidding the deployment of ASAT weapons. The 1963 Limited Test Ban Treaty and the 1967 Outer Space Treaty prohibit the placing of nuclear weapons or other weapons of mass destruction in space, and the provisions of the 1982 Salt I treaty prohibit interference with reconnaissance satellites. Negotiations on a treaty to ban ASATs were, however, broken off by the Carter Administration in 1979 after the despatch of Soviet troops to Afghanistan.

Many prominent American scientists have urged the Reagan Administration to take up recent Soviet offers to resume the stalled negotiations. Condemning last week's ASAT tests, the group argues that the deployment of small and sophisticated ASATs would make the negotiation of a verifiable treaty almost impossible. Signatories of a statement criticizing the test include Jerome Wiesner, a former presidential science adviser; Hans Bethe, a physicist from Cornell University; Franklin Long, former associate director of the Arms Control and Disarmament Agency; and Herbert Scoville, former deputy director of CIA. **Peter David**

Human rights

Philippines under scrutiny

Washington

ALLEGATIONS of gross violations of human rights in the Philippines have been made public by a delegation sent there by the American Association for the Advancement of Science (AAAS), the Institute of Medicine and four other scientific societies and human rights groups. Among the delegation's complaints are allegations of torture, "disappearances" of political detainees on the recent Argentinian model and the intimidation of health workers in rural areas.

The delegation was led by Dr Jonathan Vine, a private physician from Boston, and included Dr Robert Lawrence, director of primary care at the Harvard Medical School, and Eric Stover, staff officer of the AAAS committee on scientific freedom and responsibility. During their three-week stay in the Philippines, members of the delegation met government officials, Catholic clergy, health workers, US embassy officials, some of those in detention and also former detainees. The group visited seven detention centres and a variety of rural health facilities.

The rural health workers especially at risk are predominantly those employed on projects set up by the Catholic church to bring health care to remote areas not served by government facilities. According to the delegation, these workers are under constant scrutiny by the military, chiefly because of the suspicion that they are providing assistance for the guerilla force called the New People's Army. Many lay workers for these rural health projects have allegedly been detained and several private physicians have been arrested and held under "Presidential Commitment Orders" authorized by a decree suspending habeus corpus.

One of the incidents described in the delegation's report is that of the assassination in 1982 of a private physician, Dr Bobby de la Paz, who had operated a clinic on the remote Sumar Island. The local army command at first accused the guerillas but, in response to demands for a more thorough investigation, charged an enlisted man with the crime. The family of Dr de la Paz now claims, however, that the man thus identified does not match witnesses' descriptions of the assassin.

The delegation seems also to have been able to document several apparent cases of the torture of prisoners held for subversive activities. Its report includes a gruesome X-ray of the skull of a 37-year-old farmer who had a 4-inch nail driven into his skull while in detention. The police are said to have told the hospital to which the man was eventually taken that he had attempted suicide.

Clergy and others interviewed are reported to have said that there had been no substantial improvement of human rights in the Philippines since the lifting of martial law in 1981. The delegation notes, however, as an encouraging sign, the recent release of three scientists who had been in detention. **Stephen Budiansky**

NIH curbs drive out researcher

Washington

A FEDERAL rule that forbids researchers at the National Institutes of Health (NIH) from conducting experiments on *in vitro* fertilization with human beings has driven out the chief of pregnancy research there. Dr Gary Hodgen, a leading researcher on human reproduction who has been at NIH for 15 years, announced last week that he will be leaving at the end of June to join a research group at the Institute for Reproductive Medicine at Norfolk, Virginia. The institute was among the pioneers of *in vitro* fertilization in the United States.

Under an administrative rule adopted during President Gerald Ford's administration, federal researchers are not allowed to use the procedures of *in vitro* fertilization or to carry out experiments in which human embryos are used. NIH regulations also forbid research with human fetuses except when the objectives include assuring the survival of the fetus or the avoidance of congenital defects.

The Institute for Reproductive Medicine at Norfolk is run by Drs Howard and Georgeanna Jones, a husband and wife team who have carried out some 50 successful *in vitro* fertilizations since 1982. Hodgen is to become the institute's scientific director. Stephen Budiansky

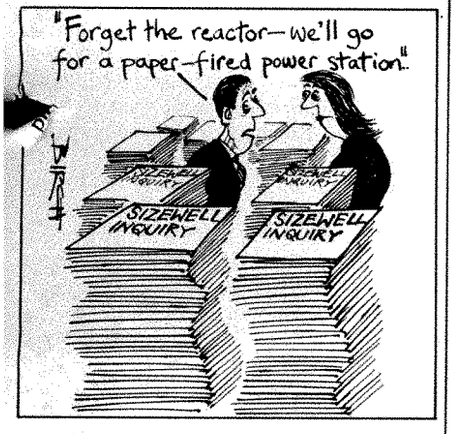
UK nuclear power



Next reactor still not decided

THE public inquiry into the application from the Central Electricity Generating Board (CEGB) to build Britain's first pressurized water reactor (PWR) in Suffolk has now entered its second year, with no prospect of finishing before the autumn. It might easily take a further six to nine months for the Inspector, Sir Frank Layfield, to complete his report and submit it with recommendations to the Secretary of State for the Environment, who will take the final decision on whether the board should be allowed to go ahead.

The inquiry is being held in a former malting-house now converted into a fine concert hall, in the tiny village of Snape in Suffolk. The planned site for the PWR is just a few miles away at Sizewell, near an existing gas-cooled nuclear power station. The inquiry hall could hold 800 spectators, but since early last year it has rarely held more than a handful of people. All the activity takes place on a raised platform where Sir Frank sits, surrounded by crates of documents and under the continual glow of spotlights, attended by two assessors and an assortment of lawyers.

CEGB has a similar posse of lawyers on the platform ready to jump up and introduce procedural points, while the objectors, running their case on a limited budget, have a smaller contingent but manage to keep the words flowing.

A great many words are involved. Every one is taken down in shorthand, and the inquiry's secretariat now estimates that, including supporting documents, it distributes 200,000 sheets of paper a week. The

proportion of these that are ever read is a different matter.

Local residents have mixed feelings about the effects of the inquiry on Snape itself, but there can be no doubt that money from CEGB has largely financed the conversion of the concert hall complex into a potentially profitable leisure centre, and that jobs will be created if the new reactor is built. Under the terms of the inquiry, the board pays for everything, from the inspector's salary down to the bus that every day runs to and from the nearest town, Ipswich. More often than not, however, the bus is empty. The one pub in the vicinity appears to be enjoying a good trade from board employees and objectors alike, although one person who is not to be seen in *The Plough and Sail* is Sir Frank Layfield: protocol demands that he is not seen dining, and presumably drinking, with either party.

The first three months of the inquiry were taken up by the electricity utility reading out its evidence, and were followed by nine months of detailed examination of the economic justification for the board's case. The objectors claim to have significantly weakened it: the board itself admits to having refined some of its assumptions but insists the case holds. Now, attention has turned to safety aspects.

Friends of the Earth, the British environmental group, has hired a barrister to make its case that the board's design is not acceptably safe, and reckons to have spent £100,000 on the inquiry so far. The group will retire from the inquiry in a few weeks' time, to be replaced by the Stop Sizewell B Association, which will concentrate on attacking the board's operational safety claims. In particular, the association will be pressing that the design should include electromagnetic filters in the reactor's coolant circuit at a cost £5 million. The filters will, it is claimed, reduce radiation doses to operators by 50 per cent.

This week, Friends of the Earth intends to raise the temperature of the proceedings by introducing a document produced by the UK Atomic Energy Authority but not publicly available in Britain. The document provisionally endorses a controversial study by the United States Oak Ridge National Laboratories which found actual rates of mishaps in reactors significantly in excess of predicted rates. Friends of the Earth says the document became available only because of an application in the United States under the Freedom of Information Act, and that the study of the frequency of mishaps at British reactors had been carried out under contract for a US customer.

If CEGB's application is granted, the result will be the introduction of a new type of reactor technology into Britain. The board's previous experience with building power stations is not encouraging, but it says that the PWR could be built in a record 19 months once it gets clearance. However, plans are already two years behind schedule and costs are rising. **Tim Beardsley**

Indian universities

Can academic politics be banned?

New Delhi

INDIA'S University Grants Commission (UCG) has called on the ruling political parties in the central and state governments to "set an example" by refraining from interfering in the internal affairs of universities. At the same time, the commission urged academics and students to avoid bringing politics into university matters. Universities cannot be run effectively, Mrs Madhuri R. Shah, head of UGC, observed, while the present "free for all" is considered to be an expression of "democracy" in the universities.

Among those spheres of academic life which UGC considers should be free from "politics" are appointments, recruitment, admissions and some administrative and financial matters.

All these spheres have, of late, become imbued with politics. Thus a recent dispute over the appointment of a new vice-chancellor at the University of Calcutta developed into a major confrontation (complete with students' strike) between the governor of West Bengal, Mr A.P. Sharma (who is *ex officio* chancellor of the university) and the Left Front state government. And a student campaign in Bangalore ostensibly demanding universal access to "scientific and democratic" higher education is closely linked with the conflict between the Janata state government and the Central Congress (I) government, and the opposition in southern India to Mrs Gandhi's hints that Hindi should replace English as India's "link language". In Assam, the All-Assam Students Union is allegedly involved in plans to bring down the state legislature.

UGC therefore suggests a formal separation of political and university life. Central and state ministers, it urges, should not seek appointment to university bodies, and university lecturers and employees who are elected to central or state legislative assemblies should be granted unpaid leave during their term of office.

University vice-chancellors should be given the "full trust" of government officials instead of, as often happens at present, the latter giving their overt or covert support to groups opposed to the university authorities. In the seven central universities (which are supported by the Delhi government), vice-chancellors should have direct access to the "highest quarters" of government, in recognition of their status as national institutions.

UGC does not spell out how these objectives might be attained, but simply appeals to the "maturity" of the political parties, calling on them to unite to save the universities "which have a key role in building the country's future". In the present atmosphere of tension between the central and state governments and the current militancy of Indian students, however, such exhortations seem somewhat utopian. **Vera Rich**

Halley's comet

Europe's hopes for second probe

GIOTTO, the European Space Agency's first interplanetary satellite, designed to intercept Halley's comet, should be backed up by a second version which could be built at relatively little extra cost, some Europeans claim. Spare parts and a spare framework are already available, and could be assembled to make a Giotto II.

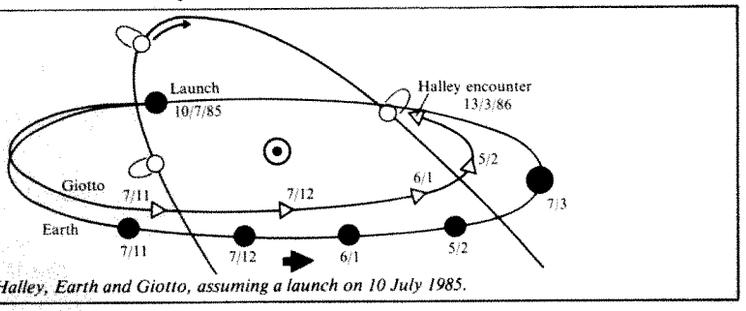
British Aerospace, prime contractors for Giotto, was not prepared last week to quote a price for such a project but, according to some estimates, a second Giotto, including launch, would cost only half as much as the current mission: another £50 million on top of the present £100 million.

The advantages of a second Giotto would be as a safeguard against the failure of the Ariane launcher, two of whose last six launches have failed. But if that launch were successful, a second Giotto could provide a matching experiment to send to another comet. The other missions to Halley, the Soviet Union's Vega craft and Japan's Planet-A and MST-5, are already double missions.

"This is a hot potato in ESA (European Space Agency) at the moment", said a Giotto specialist last week. It would put the £80-million-a-year ESA scientific programme back only a few months, he claimed, saying that it is "up to the scientific community" to decide whether it wanted to do it.

One planetologist in favour of a second spacecraft is Tony McDonnell of the University of Canterbury. He has already proposed a mission called Comex, which would be a modified Giotto II designed to intercept a number of comets by using direct orbital injection from Ariane and by carrying a liquid fuel motor aboard. Comets differ greatly from one another, McDonnell points out, some bursting, others splitting with a variety of tails and emission characteristics, and there is a danger that the Halley data will give too selective a view of cometary structure and chemistry.

ESA planners, however, take the view that any modification of the tightly-designed Giotto mission would entail its total redesign and thus destroy the advantages of using Giotto spare parts. Giotto uses a solid fuel booster which can only be fired once to reach its interception orbit with Halley, and so a Giotto II could be used effectively only for another single comet.



There may, however, be other arguments for a Giotto II. Giotto will go far closer to the comet nucleus than any other mission. (The closest approach will be less than 1,000 km, compared with upwards of 10,000 km for the Soviet and Japanese probes and for the American ISEE satellite recently diverted to comet Jacobini-Zimmer.) So, says Giotto's project scientist Ruediger Reinhard, Giotto has only a small chance of surviving the encounter.

Moreover, it is now clearly admitted, impacts with cometary dust in at least the last "tens of seconds" of the 30-minute passage of Giotto through the cometary coma to the nucleus are likely to throw out the close (1°) alignment of telemetry with the Earth, so that the last portion of data is in danger of being lost. And this assumes the dust cloud to be uniform; if Giotto were unfortunate enough to meet a jet of emission (such as are observed), misalignment would occur earlier.

There will be attempts to steer Giotto between any jets observed from Earth by taking the best straight-line path. But it is agreed that the whole exercise is risky. "We will know the risk sometime between 1830 hrs on 13 March 1986 and 0330 hrs on the next day", when the encounter takes place, said a British Aerospace spokesman.

● A rumour is circulating at the British Aerospace Dynamics Group near Bristol, where Giotto is being assembled, that Mrs Margaret Thatcher the British Prime Minister has enquired of an official whether Halley would be destroyed if Giotto targetting were so good that the satellite hit the nucleus (which is believed to be about 3 km in radius). The political consequences of such a conflagration would clearly be incalculable. But whether or not the question was actually put, British Aerospace did tackle the calculation. Little damage would be done, it seems, even though the impact would take place at 68 km per second. This velocity gives Giotto kinetic energy equivalent to about 250 kilotons of TNT, but the latent heat of melting of the cometary snowball would be some 100 million times greater.

The orbits of Halley, Earth and Giotto, assuming a launch on 10 July 1985.

European pollution

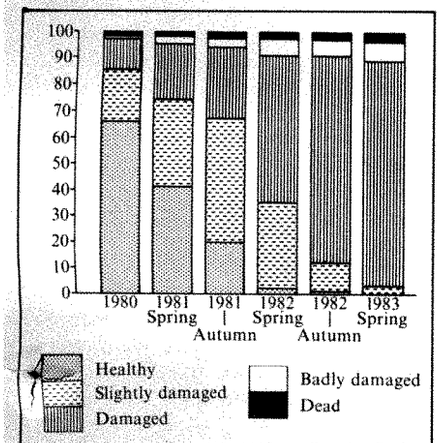
West Germany takes the lead

WEST Germany is well on its way to leading the European Economic Community (EEC) in environmental legislation. The impetus is the growing anxiety about the condition of West German forests (see figure opposite, and *Nature* **307**, 97; 1983). A government committee, *Der Rat von Sachverständigen für Umweltfragen*, has now stressed that the phenomenon "can no longer be explained on the basis of traditional forest experience", but that acid air pollution must be an important contributory cause. But there are now also fears that air pollution is increasing mortality among the vulnerable trees — the old and the very young. Mortality among the young may be especially severe in West Germany, which now has the lowest success rate for new trees in the world.

The response to the anxiety has been impressive. In a debate in the Bundestag, the Federal Minister of the Interior, Dr Friedrich Zimmermann outlined a series of measures being taken in West Germany. The federal government is spending DM56 million (£14 million) a year on research related to forest death (compared with an estimated £0.5 million in the United Kingdom. Individual *Länder* are also reacting — Baden-Württemberg, which sent a delegation to Japan to investigate power-plant desulphurizing techniques, now has three pilot plants built at a total cost of DM 60 million (£15 million) without federal or EEC support.

West Germany emits 3.5 million tonnes of sulphur dioxide a year into the atmosphere, 43 per cent of it from power stations. Regulations introduced last year set the emission levels for new power plants at 1,800 mg m^{-3} and twice that for old plant. The utilities claim the new regulations will cost them DM10,000–15,000 million (£2,500–3,740 million); 20–30 per cent of the cost of new plant is already attributed to measures designed to protect the environment.

The West German environment council is nevertheless pressing for the emission levels to be further reduced, perhaps closer to the Japanese limit of 100–500 mg m^{-3}. Even so, new regulations would reduce total annual emission of sulphur dioxide to 0.55 million tonnes a year within 10 years. (The opening by *Rheinischen Braunkohlenwerke* AG of what will be the largest brown coal mine in the world, with reserves of 2,500 million tonnes to be exploited over the next 50 years, may make that harder to achieve.)



Nitrogen oxides from vehicle exhausts are another target for current concern. One controversial estimate is that the introduction of a speed limit, of 80 kilometres per hour in general and 100 kilometres per hour for autobahns, would reduce emis-

0028-0836/84/0308-01$01.00

© 1984 Macmillan Journals Ltd

sions of nitrogen oxides by 13 per cent. But the German speed lobby has more than a little in common with the gun lobby in the United States.

In the European Communities as a whole, forest covers one-fifth of the total land area (some 35 million hectares) and provides employment for 1.4 million people. Nevertheless, the EEC is an importer of wood, bringing in 60 per cent of its needs in 1980.

The health of silver fir Abies alba *in Baden-Wurttemberg. Adapted from a report of the federal technology ministry. Observations were made on 1,675 trees.*

Damage to forests such as has been found in West Germany is widespread throughout the Community and two proposals for directives are now being considered in Brussels. One would limit emissions from large installations to 250 mg m^{-3} by 1995 and reduce total emissions by 60 per cent for sulphur dioxide, 40 per cent for nitrogen oxides and 40 per cent for dust. The height of flue stacks would not be allowed to exceed 200 metres except under exceptional circumstances, limiting long range transport of pollutants. A second proposal on nitrogen oxides would forbid air concentrations above 200 mg m^{-3} for more than 2 per cent of the time. Both proposals include requirements for strengthening the monitoring system and supplying environmental information to Brussels.

Not all the economic considerations are negative. A study commissioned by the EEC estimates that air pollution from sulphur dioxide and nitrogen oxides costs the Community US $1,400–4,200 million a year without taking account of damage to historic monuments and setting the cost of damage to public health at only $20 million. The cost of control measures for large installations is estimated at $370 million per annum for 25 years.

Sarah Tooze

● THE environment committee of the European parliament has now entered the fray on acid rain. The committee last week tabled a heavily critical report based on public hearings and written evidence, in which it claims that damage caused by acid dust and rain goes beyond even the 3–5 per cent of European community gross national product estimated by the Organization for Economic Cooperation and Development. The report calls for heavy investment in smoke-scrubbing equipment, rapid legislation to limit emissions and for more research.

On Monday, the chairman of the committee, Scottish Labour MEP Kenneth Collins, said he hoped to put heavy pressure on the European Commission, and the decision-making council of ministers, to take action. There is "widespread agreement" in the council, said Collins, but one member state — the United Kingdom — was resisting all measures in the absence of incontrovertible evidence both of acid rain damage and of the origin of the acidity.

But evidence of this kind will never be watertight, says Collins. Moreover, the United Kingdom wished to wait at least until the findings of the Royal Society study, performed in conjunction with CEGB and the National Coal Board, and this might take five years.

Collins is hoping for some pressure on the United Kingdom from the French, during the present six months' French presidency of the European Council. France is only just beginning to feel the effects of acid rain, largely in the Vosges in the east of the country, but it is more willing to act than the United Kingdom, Collins believes.

Meanwhile further pressure may come from the environment committee of the UK House of Commons, which will begin an investigation of acid rain within the next few weeks. Members of the committee will be visiting European countries including West Germany and Scadanavia.

And acid rain is now beginning to cause fears outside Europe and the United States, according to the International Union for Conservation of Nature and Natural Resources (IUCN). In response to a worldwide request for information, IUCN has learned of fears in South Africa for the Eastern Transvaal Highveld, which lie downwind of coal-oil conversion plants and coal-fired power stations centred on Witwatersrand and Johannesburg, and acidification down to a *p*H of 3.7–4.7 in San Paolo State, Brazil. IUCN has established a task force to study the worldwide effects of acidification. **Robert Walgate**

Afforestation

UK woodland policy disputed

A REVIEW of forestry policy in the United Kingdom by the British Association of Nature Conservationists has now concluded that the decline of ancient semi-natural woodland in Britain is being encouraged by a tax loophole. The review, entitled *The Future of Forestry*, endorses a Treasury study of 1971 which found that new afforestation is not justified in the national interest either strategically or economically. That report was overtaken by political events and by a government decision in favour of afforestation.

Now, according to the conservationists' report, private foresters are able, by changing ownership when a plantation becomes profitable, to switch between tax schedules so that initial costs are set against other income while productive stands are taxed only at their land value. The Inland Revenue accepts that these provisions are being exploited by syndicates of high-rate taxpayers but appears unable to remedy the situation. The annual loss through this "unscrutinized subsidy" may be up to £25 million.

Plantation with conifers, which give better commercial returns, often has damaging effects on wildlife, says the association. This is true especially where a high proportion of the land area is covered, as in parts of southern Scotland. The association recommends that the Forestry Commission, which is now disposing of many of its plantations in accordance with government policy, should cease further coniferization and that it should recommend private foresters to do likewise.

The report also bemoans the conservation grant system which allows the Department of the Environment, through the Nature Conservancy Council, to buy woodland thought worthy of conservation from the Forestry Commission, which simply returns the money to the Treasury.

The Forestry Commission has yet to consider its reply to the charges made against it, but officials say that the decline of ancient woodland will not continue under present policies and that the commission already encourages plantation of broad-leaved woodland.

Private foresters are represented by the Royal Society of Foresters in England and Wales. Mr Esmond Harris, director of the society, objects to foresters' taxation arrangements being described as "manipulation". "They are," he says, "an incentive comparable with the government's Small Business Investment Scheme." And he argues that it is "sensible" to expand the home base.

Mr Harris also challenges the view that afforestation with conifers is damaging to wildlife interests. He claims the re-establishment of goshawks in Britain and the increasing numbers of golden eagles as proof of this, citing the support of scientists at the Institute of Terrestrial Ecology for this view.

According to Dr Ian Newton of the Institute of Terrestrial Ecology, the main complaint against coniferization is when it is done in blanket fashion. He also points out that, as the golden eagle needs open ground in which to hunt, its recovery can hardly be claimed as a success for forestry policies. **Tim Beardsley**

UK research

Review of research by numbers

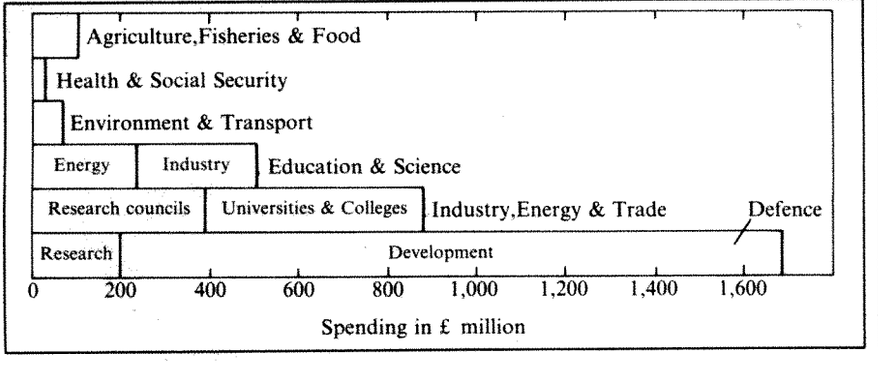
THE Prime Minister, Mrs Margaret Thatcher, announced in the House of Commons last week the publication of the first of a series of annual reviews of government-supported research and development. The need for such a review was argued in 1981 by the House of Lords Select Committee on Science and Technology, which doubted the ability of the Treasury adequately to judge individual departments' research programmes against their responsibilities.

The science and technology secretariat at the Cabinet Office has carried out the first review which enables some trends to be discerned. As a public document, the review is ostentatiously laconic, replete with figures showing the sums of money spent by various government departments (which are listed consecutively) but entirely free from value judgements.

Nevertheless, the review touches base with most of the issues now causing anxiety within the British system of research and higher education. It refers to the dual-support system (but does not say whether it has broken down), mentions the problems encountered by the research councils in paying overseas subscriptions (but recommending no specific remedies), and so on.

It is not immediately apparent whether this is the kind of document for which the House of Lords was asking two years ago, although the political problems that would arise if the Cabinet Office were seen publicly to have a view on how government departments conduct their affairs are readily appreciated.

In one respect, however, the review does break new ground in Britain by adopting as the basis for its calculations a set of definitions of basic research, applied research and development which were first promulgated by the Organization for Economic Cooperation and Development (OECD) in its "Frascati Manual".



Evidently the Cabinet Office intends to apply these definitions to the classification of British research and development, raising in the process questions such as whether the collection of data as part of some routine operation, or the application of known knowledge to concrete tasks, should be classified as research.

On the figures now published, in which the most recent records are for 1981–82, defence spending shows the biggest increase between 1973/74 and 1981/82 while the proportion of all government-supported research and development by the Trade and Industry and Energy departments fell from 21.5 to 15.4 per cent over the same period. Expenditure by the Department of Education and Science shows a modest increase, from 24.6 to 27.4 per cent of the total.

The decrease in the figures for the Department of Trade and Industry is attributed to the running down of the programmes of support for the RB-211 aeroengine and Concorde civil aircraft. The large figure for defence includes the cost of development of specific items of equipment. □

● The increase in the share of the Department of Education and Science is a surprise. At a meeting in London last week, Dr John Burnett, Principal of the University of Edinburgh, argued that in the university sector, forward commitments on research equipment now exceed the ability of the system to pay for them. But the steep drop of support from the University Grants Committee in 1981 was preceded by a period of declining support for equipment and consumables, according to Sir David Philips, chairman of the Advisory Board for the Research Councils. And Professor John Kingman, chairman of the Science and Engineering Research Council, said that the diminished ability of his council to accede to all first-rate project grant applications was in part a consequence of the increasing sophistication of equipment but that government support for particular initiatives, such as that in information technology, had come out of the science budget. Not every body agrees that academic research is being hurt however. Drs Ben Martin and John Irvine of the Science Policy Research Unit at the University of Sussex argued that the evidence for a decline is largely anecdotal, and advocated a new approach to monitoring research output: the peer-review system, they said, might not be an adequate way of making decisions about closures.

Tim Beardsley

Information technology

Europlan in doldrums

ESPRIT, Europe's £1,000-million three-year plan for joint pre-competitive research in information technology, hung in the balance earlier this week as foreign ministers clashed in Brussels over the future finances of the European Communities. Esprit was to begin on 1 January, but the wrangles over British and German contributions to the EEC budget, and over Europe's enormous agricultural surpluses (bought in by Brussels at supported prices) have brought the project to a halt. On Monday the EEC commissioner for research, Viscount Etienne Davignon, was berating ministers for ignoring Esprit and he claimed, in effect, that the economic future of Europe might depend on it.

Davignon's future certainly does, for Esprit is the *leitmotif* of his efforts to use the Brussels machinery to establish a truly European high-technology industry and infrastructure. But is his moment passing?

Esprit is already formally approved, but will have no money, probably until Britain and West Germany agree to disentangle the issue from the wider problems of the community. British officials have been hopeful, West German officials non-committal, about the prospects of this happening. Meanwhile both countries have been forging ahead with their own national plans. In both countries, companies are clearly divided about allegiance to Esprit or a national programme.

And beyond that, three European companies — Britain's ICL, France's Bull and Germany's Siemens — have already established a joint research centre (in Munich) said to be going so well that other companies are beginning to see the advantages of purely private cooperation.

In Britain, the "Alvey directorate", running a five-year £500 million programme in information technology, is getting wind of a new industrial view: that Brussels should concern itself more with the problem of setting standards (communications and design protocols and so on) than with research itself. This is but a minor part of the Esprit concept as it stands.

What seems to have happened is that the seductive possibility that one nation might win the information battle alone has taken hold. According to Mr Brian Oakley, director of the Alvey programme, Britain, with by far the fastest-growing population of microcomputers in Europe, is faced with "an incredible opportunity". This may be for the wrong reasons — people are playing "Pac-man" and "Space Invaders" rather than writing programs. But Oakley believes there is no smoke without fire.

Oakley is also proud of his team in the directorate, most of them on secondement from industry and still paid by their original employers. This arrangment has

0028-0836/84/040310-01$01.00

© 1984 Macmillan Journals Ltd

caused some companies to fear loss of confidentiality, but those have been overcome, Oakley says. Even so, after Oakley's many years in government, he can say "I have never been in such a position where I can find out so rapidly exactly what companies think". With his £500 million, this gives Oakley a position of power and pulse-taking that Davignon or his staff would clearly like to exercise on the European scale.

There is some evidence that West Germany may follow the British lead. A plan for information technology is said to be in gestation — it will probably go to the German parliament in March, after the 28 February deadline Davignon seeks for agreement on Esprit. The upshot, that the two main complainants over the EEC budget may have made their own arrangements by them, does not augre well for Esprit.

Robert Walgate

East German chemicals

Back to coal

EAST Germany is planning a return to coal and, in particular, to domestically available lignite as the basis of its chemical industry, according to a report from the German Institute for Economic Research in West Berlin. Carbon chemistry has declined in importance in East Germany since 1975, with oil being used as the primary chemical feedstock.

Last November, at a meeting of the Central Committee of the United Socialist Party (SED), party leader Erich Honecker stressed that he attached the "greatest importance" to coal gasification and liquefaction. Current plans call for 80 per cent of the growth in lignite production to be allotted as a feedstock for the chemical industry. Expansion of coal tar and, above all, carbide production is a prime objective.

According to Mr Honecker, processing chemistry — including coal and lignite — ranks with biotechnology and microelectronics among the sciences which must "increasingly permeate" the East German economy. The target date for the large-scale liquefaction of lignite is, at the latest, 1992, with a planned annual processing of 10 million tonnes of lignite into fuel and liquid feedstocks. A team of 150 scientists at the carbo-chemical centre in Boehlen is said to be working on new sophisticated processes for lignite gasification and processing.

At present, however, the return to coal and acetylene seems to be based on a revival of old methods and technologies. This, according to the German Institute for Economic Research, involves a considerable loss of labour productivity and an increase in energy consumption, since in existing plants, nine to ten tonnes of raw lignite and a "very high input" of hydrogen are needed to replace one tonne of oil.

US–Soviet space research

Moves for joint programme

MOSCOW radio's English-language service for North America has dropped several hints during the past few weeks suggesting a Soviet willingness to resume joint research projects in space. Such cooperation has, in fact, never entirely stopped. There is still some joint work on space medicine — including animal experiments on calcium loss due to weightlessness — and Soviet–American meetings of planetologists involved in Venus studies.

The recent hints suggest, however, that the Soviet side would like to see a resumption of plans for a joint manned mission. One commentator noted that there was at one time a plan for a link-up between the US space shuttle and a Soviet Salyut station. This, he claimed, was "unilaterally suspended" by the American administration, which has "increasingly been expanding military space projects at the expense of scientific research in space".

The same attitude of blaming the Americans for the cessation of these plans was adopted by Vladislav Dobrosel'skii, head of the external relations administration of the Soviet Academy of Sciences. He maintained that, in spite of highly-publicized official embargoes, the Washington government has quietly maintained a policy of preserving exchanges and contacts in areas where the Soviet Union is undoubtedly ahead. In the field of space medicine and biology, in which Soviet achievements are "obvious", the Soviet Union had however been guided by "humanitarian motives" in making their experience and knowhow available to the Americans.

Ostensibly, Dobrosel'skii's call was for a restoration of "broad scientific ties" between the United States and the Soviet Union. His stress on the Soviet lead position in space, and the advantages which, even now, the Americans receive from it, suggests that renewed cooperation in space was the prime purpose of the broadcast.

What political ambience the Soviet Union would demand as a prerequisite for a major joint space experiment has not, so far, been spelled out. (So far the commentators have simply urged that such cooperation would be conducive to peace and detente.) Dobrosel'skii himself urged that cooperation should be "on a footing of equality, without any discrimination" and "free of contingency fluctuations" (presumably of political origin). It is possible, therefore, that the suggestions were intended as a warm-up to the latest round of "confidence building" negotiations which opened in Stockholm last week.

It should be remembered, however, that in 1982, a Moscow radio commentator hinted that the United Kingdom could qualify, like France and India, for participation in the manned "Interkosmos" programme — provided it first rejected the siting of US missiles on its soil.

If the possibility of a joint United States–Soviet major space effort goes further than the recent preliminary kite-flying, it seems highly likely that some concession on arms limitation will be demanded by the Soviet side as a prerequisite to participation.

UK observatories reprieved

GROUND-based astronomers in Britain and particularly those at the Royal Greenwich Observatory (RGO) should be breathing a sigh of relief this week. The Willmore panel set up to advise the Science and Engineering Research Council (SERC) on the future of the British observatories has recommended that RGO, the Royal Observatory Edinburgh (ROE) and Rutherford Appleton Laboratory (RAL) should all continue to be supported by the SERC. This recommendation has been accepted by the body directly responsible for UK astronomy, SERC's Astronomy Space and Radio (ASR) Board, thus stilling fears that RGO might be abolished in the near future (see *Nature* 301, 102; 1983).

The final decision, morever, rests with the council, due to meet in mid-February, although there is no reason to believe that it will not follow the recommendation. But the observatories will probably not escape totally unscathed, for the plans now laid for instrumentation of the new telescopes at La Palma and Hawaii will probably be cut back, or be streched out. Those working at RGO, who have been expecting to co-ordinate the remote operation by satellite of the La Palma telescopes, will for example be displeased by the news that the initial demonstration of this technique, both for La Palma and for the millimetre-wave telescope being constructed in Hawaii, will be carried out at the Edinburgh Observatory.

While these decisions relate to the long-term future of the ASR Board's activities, immediate problems remain. Deficits arising from the effects of exchange rate fluctuations on international subscriptions have been partly compensated for by the Treasury, to the tune of £7 million. But for the financial year 1984-85, the board still has to cut about £2 million from its original estimate. To achieve this, the board intends to cut funds from research grants by 5 per cent, RGO and RAL manpower by about 10 per cent and 15 per cent respectively and other institutional costs by about 10 per cent.

India's science defended

SIR — Dr Malviya (*Nature* **306**, 10; 1983) says that scientists in India are "not terribly science-minded" and that there is no competition among them. I imagine that, science being universal, "competition" ought to be among the scientists in the world rather than among those of a given country. And if one wishes to compete for recognition in science, one obviously ought to be science-minded.

I believe that Indian scientists working in India are not all that bad. During the past decade at least seven of them have been elected to the Royal Society of London, others as fellows of academies in the United States, the Soviet Union and in European countries while some hold high offices in international scientific unions and the like.

India is a vast heterogeneous nation with pockets of brilliance where the scientists are very good, and also many places of mediocrity, not strikingly different from the spectrum of the quality of Indian expatriates abroad: some very good and some mediocre.

On the hostility of Indian scientists towards their countrymen abroad, the Indian National Science Academy has about 30 of them as fellows in a total membership of some 500, while the Indian Academy of Sciences, in its total fellowship of about 490, has more than 30 Indians settled abroad. And we have not heard of any such hostility from the more than 100 expatriate Indian scientists (Dr Malviya included) who have visited our laboratory at our invitation in the past 2 years.

The question of improving the quality of Indian research necessarily involves the creation and generous support of centres of excellence and this infusion of new blood in its universities and research centres by the creation of additional research chairs with good salaries and facilities. The last idea has already been taken up in the form of a cadre of "research scientist" positions at existing universities. Such positions are open to both residents and expatriates, as they should be. No special consideration for expatriates seems to be necessary.

In considering how to improve the quality of scientific research in India, an appreciation of the existing efforts and problems is essential. Simplistic solutions or blanket condemnations are of no value. I am thus particularly dismayed at Dr Malviya's claim that the people who control science in India are scientifically most incompetent. Those concerned, many of them FRSs, include those who brought in the green (and now the white) revolution, who have put up Indian satellites and sent Indian research vessels to the Antarctic, set up nuclear plants for power production, trebled the amount of irrigation water in 30 years and controlled communicable diseases.

These scientists advise the central cabinet of ministers on scientific matters. And it is this scientific competence, utilizing the science and technology base within, that has made India self-sufficient and not a market-place for giant multinational manufacturers.

Let us therefore not tie ourselves into knots of self-flagellation and also keep our temper — the scientific kind — so that we can attempt to solve our problems. (Incidentally, the issue of *Nature* that carries Dr Malviya's letter also carries an article on the cloning of rice embryo histone genes by Indian scientists working in India.)

Who's playing God?

SIR — In reviewing Paul Davies's *God and the New Physics* (*Nature* **305**, 833; 1983) Professor McCrea eschews "any close critical assessment of the work". This approach is akin to that followed by most theologians and practising religionists; to construct elaborate hypotheses based on conjecture and wishful thinking and not squarely to examine the evidence.

While not discounting Dr Davies's scholasticism, it seems a bit over-stated for McCrea to experience "humility" in the light of Davies's "courageous thinking". How courageous must one be, in these times, to espouse ideas dating back to Epicurus? Davies, like many who have preceded him, is merely attempting to intellectualize and dilute the god-concept in order to make it more palatable to those emotionally-weak individuals whose educations would normally preclude such irrational ideas, but who are nonetheless attracted to Universe-schemes which give them a sense of value and purpose other than that which they are able to create for themselves.

This type of accommodation of science by religion has been repeatedly used by the Church throughout the ages in order for it to remain afloat in a sea of scepticism. Any definition of "God" which is interchangeable with "Universe" (another vague term) or "all in all" is completely useless both as a separate concept and as a source of meaning in human existence. Is it not better respectfully to retire such antiquated ideas?

In a decade when science and education are continually being undermined and assaulted by creationists and other pseudo-scientists, it is high time that the scientific community should cease patronizing religion, which we have seen can be quite a formidable opponent to progress and the betterment of the human condition.

Inviable usage

SIR — I share the concern indicated by Vimala Sarma, regarding the obfuscation in the recent report of the NH & MRC of Australia, which has adopted a recommendation on rules for fetal research (*Nature* **306**, 308; 1983).

Viable, which means capable of maintaining life, is an adjective which may be applied to the embryo, fetus or neonate; for, in the appropriate environment, each is indeed capable of maintaining its life, given adequate oxygen and nutrition, at least. "Previable" is a term which has no scientific basis, either in embryology or neonatology, to explain a given status of an embryo, fetus or neonate. The report itself indicates as much when it states — "dissection of the fetus should not be carried out while a *heartbeat* is still apparent or there are other *obvious* signs of life".

This seems a clear case of scientific jargon obscuring meaning.

New words for old

SIR — Your offer (*Nature* **306**, 134; 1983) to make space available for comment on the abuse of language is welcome. I submit a plea that when new words are coined, they should be unambiguous. It is a pity that the pedantic rule against mixing languages is so often violated. *Prebiotic* may be cited as an example: *probiotic or prevital* are preferable.

Some words, for example, *dyke* and *watershed*, have antithetical meanings. In Britain, *watershed* means the line separating catchment areas, and that is the metaphorical meaning in the United States. When used non-metaphorically in the United States, it means a catchment area. So *watershed* is a meaningless word in an international journal. Chemical logic has introduced a few possibilities of ambiguity in written English, although context usually distinguishes the two meanings of such words as *periodic* and *retinal*.

Ambiguity could be avoided if editors took more care to correct the carelessness or ignorance of authors. As T.S. Eliot remarked: ". . . (words) slip, slide, perish, decay with imprecision . . .". We are in danger of losing the distinction between *enormity* and *enormousness*, between *militate* and *mitigate*, and between *suck* and *suckle* (the baby sucks, the mother suckles). The original clearly defined meaning of *visualize* will be lost if the word is stretched to mean to stain or otherwise make visible. Perhaps another word is needed to carry that meaning — I suggest *iconize* or *phanerize*.

Dispute over scale of Universe

Controversy continues about the scale of the expanding Universe, with the two camps separated by a factor of two. Resolution of the conflict is more urgent than the disputants acknowledge.

OF all the natural constants, Hubble's constant must be the least deserving of the name. Those not directly concerned with the measurement of the distance-scale of the Universe may be forgiven if they harbour the impression that, for the past quarter of a century, the extant value of H_0 has stubbornly refused to settle down within some bounded range of all possible values, eventually to approximate ever more closely to what might be called a true value. Instead, successive estimates of H_0 seem to have fluctuated between two extremes differing numerically by a factor of nearly two.

Behind each value, there is a different school of opinion. Sandage and Tammann, whose latest estimate of Hubble's constant appears in this issue on page 326, are among those who hold that H_0, the measure of the rate at which the expansion velocity of the Universe increases with distance, is unlikely to be very different from 50 km s^{-1} per megaparsec (abbreviated to Mpc). The opposing school, represented for example by Dr G. de Vaucouleurs of the University of Texas at Austin, considers that the value of H_0 is more likely to be twice as large, approximately 100 km s^{-1} Mpc^{-1}. In some ways, the latest contribution from Sandage and Tammann appears to be a direct response to a challenge issued by de Vaucouleurs two years ago (*Nature* **299**, 303; 1982), when he argued that a careful examination of the hydrogen-line radio-emission from receding galaxies should provide one of five crucial tests of the conflict between the two distance scales.

This long-standing issue is unlikely, however, to be settled by the appearance of just one more contribution, and neither Sandage and Tammann nor de Vaucouleurs should be blamed for that. For one thing, the problem is uncommonly difficult, as Hubble himself recognized more than half a century ago. Essentially it is that of attempting to construct a distance scale applicable to objects in the Universe so distant that yardsticks usable on smaller scales (for example within our galaxy) are not directly applicable. Instead, they must be translated into secondary yardsticks by processes never free from assumptions about the physical nature of extragalactic objects (and even the space between them).

Then, the problem seems always to become more complicated. While the uniform (in space) and constant (in time) expansion implied by the definition of the Hubble constant may be a good first approximation to the Universe in the large, only in the past fifteen years has it become plain that we perforce look out at the Universe from an exceptional place, one near enough to the Virgo cluster for the motions of most nearby galaxies (on which previous estimates of distance have largely been based) to be streaming towards its centre of gravity, and even for the motion of our own galaxy (as measured by the anisotropy of the microwave background radiation) to be influenced as well.

Inivitably, these tenuous chains of inference run into serious trouble in the most distant reaches of the Universe, where the galaxies may be physically different (witness the quasars) from those in our immediate neighbourhood. One practical consequence is that people seem for the time being to have abandoned hope (still strong less than a decade ago) of being able to determine accurately from direct observation any but the first linear approximation to the expansion of the Universe. The Hubble constant may be uncertain, but the the range of values admissible for the deceleration of the expansion — the next approximation — is so great that the argument whether the Universe is open or closed has reverted entirely to the theorists.

The article by Sandage and Tammann will find a wide hearing simply because it offers a novel test of a sensible prediction of the relationship that should exist between the intrinsic luminosity (or mass) of a galaxy and the maximum velocity of its interstellar gas, predominantly hydrogen. Crudely, the greater the mass within some distance of the centre of a galaxy, the greater will be the gravitational potential at that distance so that, other things being equal, the greater will be the velocity of freely moving material at that point.

So, according to what is known as the Tulley–Fisher relationship, it should be possible to infer, from the broadening of say the 21-centimetre hydrogen line, the spread of velocities of hydrogen clouds within the galaxy and that, by comparison with other galaxies of the same type, should yield an estimate of the intrinsic magnitude of the distant galaxy. The use of the Tulley–Fisher relationship is not of course new; two years ago, de Vaucouleurs used exactly such an argument to support his view that the Hubble constant is roughly twice that now quoted by Sandage and Tammann.

How can such discrepancies arise in the analysis of the same data? And how will they eventually be resolved? The obvious difficulty is that the process of extending the distance scale beyond nearby galaxies is far from being objective. Whatever physical principle is used to help determine the intrinsic brightness of a distant galaxy, people will eventually be driven to select, from among all galaxies for which measurements are available, a sample which can be held to be comparable with each other.

The snag, as the experience of past decades has shown, is that this process of selection can also be a source of bias, involving as it does explicit or even hidden assumptions about the physical reasons why one type of galaxy differs from another. Indeed, these chains of inference are so complicated that many of the minor controversies that arise within the ambit of the larger controversy are discovered, in the end, to have arisen because some set of apparently independent measurements is found to hang on a few or even a single one of them.

The only remedy is the old remedy — more data. In the long run, the construction of a reliable distance scale will require such a detailed study of the properties of the galaxies involved that the propriety of the comparisons made can be verified directly. The search for novel ways of comparing the intrinsic brightness of near and far galaxies should of course continue (as it will), but there should by now be enough experience, most of it disappointing, for the practitioners to know that there is no magic solution on the cards.

What, in the meantime, is to happen to the controversy between the opposing camps, each of which is convinced of the correctness of its own estimates of the distance scale? Sandage and Tammann point out that their own estimate of Hubble's constant has the virtue of suggesting an age for the Universe as a whole which is more nearly in agreement with Astrophysical estimates of the age of the objects which it contains than the shorter time-scale implied by the longer distance scale of de Vaucouleurs and others (which does not, of course, prove that it is correct). This circumstance seems to infuriate the other camp, with the consequence that the controversy is no longer seemly. The ideal would be that those concerned should acknowledge that the crying need is for a reliable distance-scale, not for a proof that one or other of the two candidates now in the field is the better.

Archaeology

Clues to recent human evolution from specialized technologies?

from Marek Zvelebil

A WEALTH of new studies of the technology used by hunters and gatherers to procure their food are making it possible to guess what part advances in technology played in human evolution. Particularly interesting are two recent analyses by R. Torrence[1] and R. Dennell[2], building on earlier work by Binford[3–6], of the way in which the development of specialized stone tool technologies allowed foraging societies dependent on a narrow range of resources to live successfullly in cold northern climates. The analyses show that devoting time to the production of special tools may have made possible the replacement of the neanderthal by modern man during the last glaciation, and the colonization of sub-Arctic areas some 30,000 years ago.

In their efforts to survive, prehistoric societies employed various technologies. The most ancient of them — that of stone — has been in use for more than two million years. But the making of tools takes time — time which could be spent on other activities, including the search for food. Benefits derived from the use of any range of tools must be carefully weighed against the time and effort needed to make them, and their manufacturer and the search for raw materials must be organized so that they complement other activities required for subsistence. In favourable environments, where resources are evenly distributed in space and over seasons, people can usually obtain their food with the aid of only relatively simple technology. Using data collected by Oswalt[7], Torrence[1] has shown that the use of simple general-purpose instruments and weapons is associated with hunter-gatherer societies that live in tropical and sub-tropical climates, where most of the food comes from stationary reliable plant resources. In contrast, where resources are seasonal and mobile, as in the Arctic and sub-Arctic, highly specialized complex tools are found that require considerable skill and planning to produce.

To exploit seasonal and mobile resources (the characteristics often occur together, as in migratory herbivores, water-fowl, seals or anadromous fish) requires a long time: both to locate prey (search time) and to capture it (pursuit time); but the time available is limited. Foragers can increase the reliability and productivity of their subsistence strategy by using time-saving devices: by budgeting their time and by preparing in advance more specialized but also more complicated tools, designed for each of the number of tasks involved (Fig. 1). In societies dependent on stationary ubiquitous resources, time is not so important and the use of a complex and specialized technology would not bring benefits that would justify the time and effort spent in its development.

In a recent publication, Dennell[2] linked the technological developments of the Upper Palaeolithic with the conceptual advances which marked the difference between modern man and neanderthals. Compared with the Mousterian — the technology which spanned the middle Palaeolithic — upper Palaeolithic industries were more complex: the number of techniques used for working raw materials increased, as did the range of raw materials; and the number of components making up an artefact increased, as did the diversity of tool types. The number of stages involved in making artefacts increased significantly; according to Dennell[2] it is this feature that marks the crucial difference between middle and Upper Palaeolithic technologies. The middle Palaeolithic Mousterian was essentially an expedient technology: tools were made for immediate needs in a short sequence of single-stage operations. It is perhaps for this reason that raw materials which required a large amount of time and labour to make into artefacts, such as bone, ivory or antler, were not used extensively in tool making until after 30,000 BP. In contrast, upper Palaeolithic artefacts were made in anticipation of future needs in a series of temporally and conceptually separate stages, employing a variety of different techniques and separate manufacturing processes. This required advances in planning and, possibly, advances in manual dexterity that might have been beyond neanderthals' mental and physical capabilities.

The similarity between the new upper Palaeolithic technology and the technology used by modern foragers in cold environments seems remarkable until we realize that both populations were trying to cope with the same type of time-stressed seasonal environments: the cold temperate and Arctic habitats, where resources tend to be not only seasonal and migratory but also to contain fewer spec[illegible] These characteristics mutually reinforce each other in encouraging the development of specialized technology: seasonality and

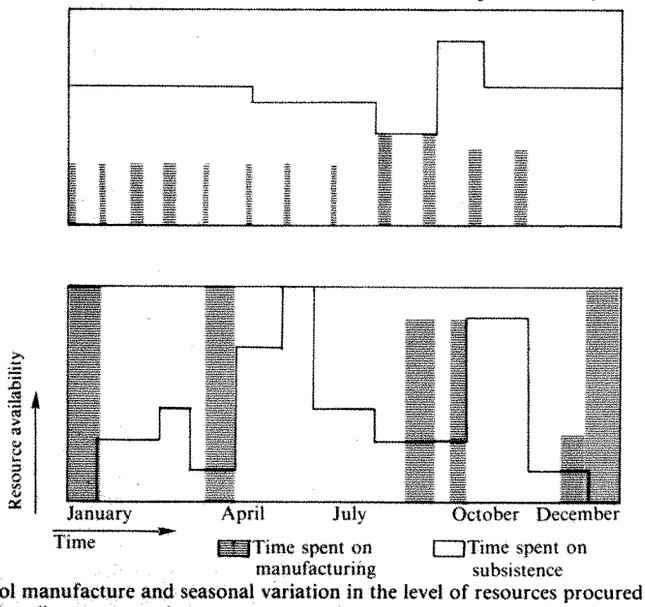

Fig. 1 Tool manufacture and seasonal variation in the level of resources procured. The upper diagram describes a system where permanent stationary resources are exploited using generalized technology (as, for example, in tropical gatherer communities). Little time is spent on manufacturing, which is evenly spread throughout the subsistence activities. The lower diagram shows how seasonal and migratory resources are exploited using specialized technology (for example by boreal hunter-fishers). Here, food procurement time is at a premium. Manufacturing time is greater and is located in periods of minimum subsistence activity.

mobility because specialized technology saves search and pursuit time; low diversity because specialized technology acts as an insurance against failure.

Organizational changes brought about by the use of specialized technology[1,5] must have aided upper palaeolithic man considerably to cope with the cold and seasonal environments of the temperate zone during the later part of the last glaciation[8]. In competition with these more flexible cultural adaptations, the physiological adaptations of neanderthal man to cold climate[9,10] proved inadequate. Assuming that in western Europe we can equate neanderthal man with the old Mousterian technology and modern man with the new — an assumption not universally accepted[11] — then the disappearance of neanderthals around 35,000–30,000 BP can probably be attributed to their failure to compete successfully with the better equipped *Homo sapiens sapiens* for the mobile and seasonal resources of the last ice age.

The observations made by Dennell and Torrence have some further implications. The failure of the neanderthals may illustrate the inability of human populations to survive and prosper in cold and seasonal climates without the aid of complex and specialized technology. There is no evidence of human occupation of Siberia before 35,000 BP, while the earliest reliable evidence for the presence of humans in North America dates to 27,000 BP (refs 12–14). It may be that successful colonization of these sub-Arctic regions (as they then were) could not have been accomplished without the technological and organizational advances attained by modern man. □

Optical bistability

Towards the optical computer

from S. D. Smith

NEXT month (21 and 22 March) the Royal Society will hold the first European conference devoted exclusively to optical bistability and photonic logic. This is a mark of the growing appreciation of the potential of these devices in the design of new kinds of computers that will not merely be faster than, but different from, the machines now being used.

Sequential binary logic has had success enough in the fields of signal processing, transmission and computing using one-dimensional electronic circuits as to be now accepted as one of the vital elements of our new industrial economies. But this familiar method, because it is sequential and because the signals are confined to a conducting wire, is clumsy and primitive. The disadvantages are overcome, say for a computer calculation or in building up a television picture, only by means of a large number of high-speed switching operations.

The possibility that optical devices might be superior goes back to 1969, when Abraham Szöke and colleagues at MIT put forward a first statement of a principle of optical bistability[1] based on the combination of nonlinearity, represented by saturable absorption, with positive feedback provided by an optical resonator. This led to the simple idea of an optical device consisting of a Fabry-Perot interferometer with an absorbing spacer layer illuminated by a laser and having two stable states — one at low power in which there is no interference and low transmission and one in which, at high power, the spacer absorption is saturated, constructive interference can take place and both transmission and internal intensities in the resonator are large. Once reached, the second state could in principle be maintained with a lower power than required to achieve it. The output and input of the device are thus related by a bistable loop (Fig. 1).

In reality, the effect was not observed until 1976, when a bistable optical effect was found in sodium vapour at the Bell Laboratories[2]. But analysis showed that the effect was due to refraction, not absorption, almost coincidentally with the publication of a theory of refractive optical bistability[3] based on the idea that refractive index can vary with light intensity. In retrospect, it turns out that absorptive bistability is much less easily observed than refractive bistability, basically because of the greater sensitivity of the interferometric effects when a resonator length is tunable through the intensity dependence of refractive index.

The device operates as follows (see Fig. 2). An interferometer is illuminated by a laser at a wavelength slightly detuned from resonance at some intensity (called the 'holding power'). Increase of intensity changes the optical thickness, moving the device towards the resonance. But, as resonance is approached, the ratio of the internal field to the incident field increases as interference becomes more constructive. Because it is the internal intensity that causes the nonlinearity and hence the optical thickness change and the rate of tuning, positive feedback is provided. The rate of tuning increases dramatically and the resonator can switch in a bistable manner.

The intrinsic interest of optically bistable effects caused an outburst of theoretical work, mainly concerned with two-level atomic systems, but the most significant steps towards a potential new technology were perhaps our discovery in 1976 at the

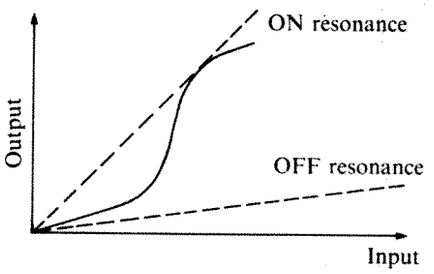

Fig. 1 Schematic relationship between input and output light intensities for a bistable device (full line). The sharp increase of output with input in the middle of the diagram explains how such a device may be used as a fast switching device.

Heriot-Watt University in Edinburgh of giant band-gap resonant nonlinear refraction in a narrow-gap semiconductor[4] and of similar effects, albeit a thousand times smaller, near the exciton frequency in GaAs by a Bell Laboratories group[6] in 1979.

The first discovery, giving a nonlinear refractive index n defined by $n = n_o + n_2 I$ of the order $n_2 = 1\ \mathrm{cm}_2\ \mathrm{kW}^{-1}$, meant that nonlinear optics was transformed from megawatt to milliwatt powers. The origin of this previously unnoticed effect lies in the 'blocking' or saturation effect of promoting electrons into states near the band-gap, with consequent large changes in the real part of the dielectric constant. The development also meant that devices a few micrometres in dimensions could be constructed. Thus in 1979 we[5] and the group at the Bell Laboratories[6] simultaneously reported the observation of optical bistability in small semiconductor resonators. Our group at the same time described 'transphasor' (that is, optical transistor) action with a two-beam signal gain of about 10 (see text below and Fig. 6).

These experiments have now set the scene for a complete family of optical circuit elements[7] (see Figs 3–5). Simply by adjusting the initial detuning, either single-valued characteristics with steps of slope greater than 1 (gain) or bistable loops of variable width can be obtained. Moreover, a system such as InSb at 77K can be held by

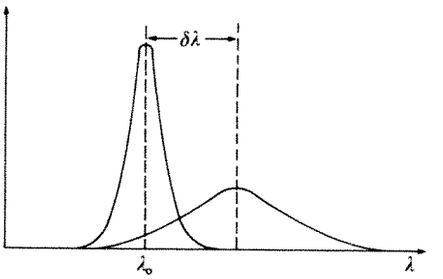

Fig. 2 Change of state of nonlinear refractive optical resonator with increasing light intensity. The refractive index n is $n_0 + n_2 I$, where n_0 and n_2 are constants, and I is light intensity. Increasing intensity increases n and thus reduces the wavelength λ to coincide with a value λ_0, an integral sub-multiple of the length of the resonator.

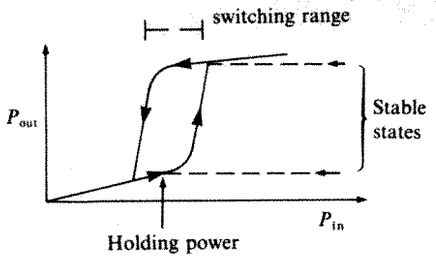

Fig. 3 Bistable optical element as a binary memory device.

a continuous bias beam at a given point on the characteristic and then addressed by a light pulse, and such a system was used in 1982 to demonstrate optical AND/OR and NAND/NOR logic gates using both reflection and transmission[8].

In the past year, devices that function at room temperature have been made from a variety of systems such as GaAlAs multiple-quantum-well systems (Bell and Arizona, at 0.8 μm), Te (Jena, at 10.6 μm), InSb (Heriot-Watt, at 10.6 μm) and liquid crystals (Berkeley, visible). At the same time, other narrow-gap semiconducting materials have been introduced such as CuCl (Strasbourg, visible), CdS (GTE and Frankfurt), CdHgTe (RSRE) and InAs (University of Southern California) at cryogenic temperatures. The speeds of these devices and the light intensity required vary considerably, and with the present rapid progress, it is too soon to know which materials will prove most suitable for which purpose. But many systems suggest switch-up times of the order of picoseconds. Fast switch-down has yet to be confirmed, but seems possible.

Novel approaches to either the geometry of the feedback process (such as focusing) or the nonlinearity have also recently been pursued. One intriguing development has been the use of radiation pressure[9] on a freely mounted mirror forming part of a Fabry-Perot device (Max Planck Institute for Quantum Optics, and the University of Munich). In this experiment, the length of the resonating cavity is changed simply by using the radiation pressure impinging on the mirror *in vacuo*. The system is clearly sensitive to vibration and, indeed, has already been recognized as constituting a sensitive seismometer. Direct conversion of acoustic waves to optical modulation (a microphone for optical fibres?) is another possibility.

With the development of this growing family of optical devices based on optical bistability, all the elements required to make an optical computer have now been demonstrated. Where will this lead? If devices based on optical bistability are to compete with those of other switching technologies solely in terms of speed and power, their application would be limited by the continuing advance of silicon technology. But optical devices have qualitative advantages. A lens or mirror can easily communicate thousands of channels of information in parallel, while one optical beam can be passed through another without interference.

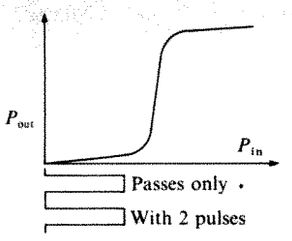

Fig. 4 Optical logic element as an AND gate, giving significant output only when two pulses separately not intense enough to switch states coincide in time and exceed threshold.

By contrast, electronic signals must be individually guided and protected from interacting, and in the design of future electronic computers, switching speeds will certainly increase as very large-scale integration (VLSI) proceeds, but so will the band-width needed for the interaction of components. But communication usually entails some circuit capacitance, and as sizes are reduced, time-constants increase.

In designing a computer architecture to take advantage of the new optical circuit elements, it may well be that interconnection time and the use of parallel channels will be the key points. The 'van Neuman bottle-neck', perhaps the fundamental limitation of digital computers, is the trade-off time for interconnections needed to make up for the inability of electronics to support multiple communications channels in parallel. These are the processes that limit the time taken for a computer to perform a given task.

At this stage, only general statements can be made about the form which an optical computer may take. One of the concepts being investigated, for example, is a two-dimensional array of optical NOR gates with optics, including prisms and lenses, capable of offsetting an output image of the NOR gate array by one pixel and then feeding the output image into the input. More prosaically, if the performance of optically bistable devices at low power

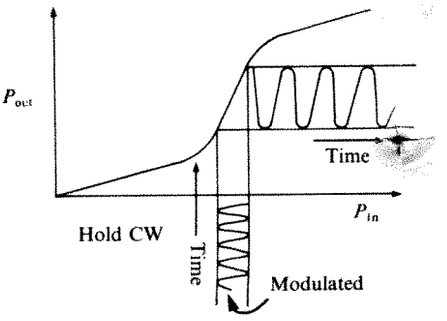

Fig. 5 Transphasor (signal amplifier) in which optically bistable element is held at linear part of input–output relationship. The gain of this device is given by the slope of the curve and may be as great as 10,000 (see text).

levels presently obtained in the infrared can be reproduced with suitable materials in the visible spectrum, technically simple optically-addressed display technology would become available. Power limiters for laser pulses are certainly a practical proposition and, since the most recent work at Edinburgh has demonstrated a transphasor gain of 10,000, all-optical repeaters for fibre communication lines may be possible. Further, incoherent light, which could be in the form of an image, has been shown to cause bistable switching and amplification strongly suggesting that the technique will be useful in image processing. □

GEOGRAPHICAL NOTES

THE first report of Prof. Hull, dated from Gaza, January 1, has been received. It is necessarily brief, the details being reserved for the full report to follow, but it announces the success of the expedition so far. The professor has made a complete geological survey of the Wady Arabah and the Dead Sea, with a traverse across Southern Palestine. Capt. Kitchener, R.E., who accompanied him, has made a trigonometrical survey. Akabah he found to be laid down too far south; the south part of the Dead Sea as shown on the maps, is quite out of its true shape and position, and the Lisan has to be shifted three miles. From Gaza, when the rest of the party were in quarantine, Capt. Kitchener rode back to Egypt, accompanied by four Arabs only. He took a previously unknown route, particulars as to which will follow, and arrived at Ismailia after a ride of 200 miles. He was everywhere well received by the Arabs, who took him for a cousin of Sheikh Abdullah (the late Prof. Palmer), whose memory is still revered among them, and whose murder they still deplore. They are also reported to be deeply impressed with the energy and pertinacity of Sir Charles Warren's pursuit of the murderers.

Immunology

Mechanism of T-cell tolerance

from Roger B. Taylor

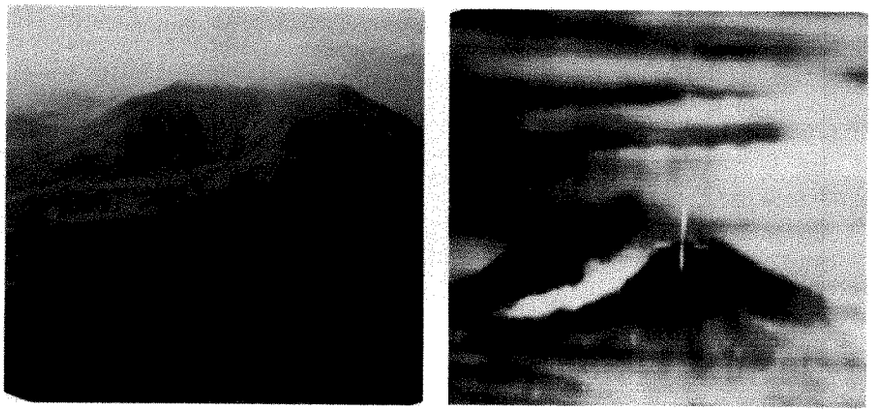
IN spite of the burgeoning literature on suppressor cells and immunological networks, there has been persistent support for the notion that responsive lymphoid cells may be specifically deleted. This term is now broadly interpreted to mean some internal change occurring in the cell to render it either temporarily or permanently inactive.

We already know that B cells, especially in their immature stages, can enter a condition of lasting unresponsiveness — sometimes accompanied by a defect in the expression of receptors. So far, however, the evidence for deletion of helper T cells has been restricted to experiments *in vivo*, almost entirely in mice, using mammalian serum proteins in high dosage as tolerogens.

To be certain that no suppressor influences are at work one should ideally study tolerance in monotypic cell populations, and preferably clones, *in vitro*. It was therefore a breakthrough, important in more than one sense, when a group working at University College, London, recently achieved the induction of tolerance in human helper T-cell clones *in vitro*[1].

These clones were specific for peptides derived from the influenza haemagglutinin molecule, and were propagated by stimulation with the specific peptide in the presence of unseparated human mononuclear cells which served as antigen-presenting cells. After such stimulation the cells would both exhibit a proliferative response and help B cells to produce antibody. Lamb and his co-workers then tried incubating the clones with high concentrations of the peptides, in the absence of the human mononuclear cells. On subsequently testing the response to the usual low stimulatory concentrations in the presence of the human mononuclear cells they found that the T cells had become specifically unresponsive. The tolerized cells would continue to divide in the presence of interleukin-2 but only for a period of 1–2 weeks, after which their viability declined. A critical finding was that the 'tolerized' cells had lost the surface marker T3 which is thought to be closely associated with the antigen receptor[2]. It confirmed that some demonstrable change had occurred in the cells, and thus argued that the tolerance was not due merely to blocking of the receptors by the high concentration of peptide. A parallel finding was made by Schlossman's group in Boston, who induced a similar state of deletion in human T cells by means not of antigen but of anti-receptor antibodies[3].

Against this background, interest now focuses on the mechanism by which such deletion comes about. A pertinent report has recently appeared from Schwartz's group at the National Institutes of Health, on cloned mouse T cells[4]. These clones, specific for pigeon cytochrome *c*, were propagated by stimulation with this antigen on irradiated mouse spleen cells or a B-lymphoma cell line as antigen-presenting cells. The proliferative response was measured in the presence of varying concentrations of both antigen and the relevant Ia. (The latter was varied by changing the numbers of presenting cells, blocking with anti-Ia antibody, or by the choice of cells homozygous or heterozygous for the relevant Ia.) Bell-shaped curves were obtained, in which the response was inhibited at high concentrations of either antigen or Ia or of both. A clear relationship emerged whereby the response depended on the product of the concentrations of antigen and of Ia. One implication is that a physical product of these two molecules must be the critical driving force for T-cell activation. For the high-dose inhibition to be classed as tolerance, it would need to render the cells refractory to subsequent stimulation with optimal doses. This has not yet been reported. Nevertheless the similarity to the human T-cell work is obvious.



The question now arising is how the T cell is inhibited. Does the occupation of a high proportion of receptors release a negative signal to the cell interior? Or does intense stimulation cause the cell to release critical amounts of an external feedback signal? The authors suggest that immune interferon could serve as such a feedback control — particularly as its production is not subject to the same degree of inhibition at high doses of antigen as the proliferative response[5]. There is no evidence so far, however, that the inhibitory effects of interferon on immune responses can persist long enough to be classed as tolerance.

Interferon can also enhance immune responses, as exemplified by a paper in this issue of *Nature*[6] (see p.381). It is shown that interferon both increases antibody responses *in vivo*, and also increases the expression of Ia on an antigen-presenting macrophage cell line. The authors suggest that the effect of interferon on the antibody response is achieved by virtue of its effect on Ia expression. If this is the case, then the bell-shaped curve derived by Schwartz and colleagues leads us to expect that, at high concentrations of antigen, interferon should aid the induction of tolerance rather than immunity. Its activity might then be seen as to shift the curve to the left, and so influence the quantity of signal delivered via the receptors rather than acting itself as a negative signal. This might also be the role of a variety of other 'adjuvant' influences, many of which can have either positive or negative effects in different circumstances. □

Latest view of Mount St Helens

MOUNT St Helens photographed during its eruption on 18 May 1980 in normal light (top), and in a recently-released US Navy infrared image. White areas on the infrared image represent hotter areas of the volcano and allow the lava flow near the crater and thermal events not usually seen by the naked eye to be detected. The infrared image was taken from a Hughes A-6E Intruder aircraft using its 'Detecting and Ranging Set', a thermal imaging sensor which, when not photographing volcanoes, helps the Intruder's aircrew see and attack surface targets at night or through smoke and haze. □

Molecular biology

Genetic noise in evolution?

from Darryl Reanney

IN 1949 Shannon[1] published an important theorem which states, in essence, that information cannot be transmitted over long periods of time without experiencing some deterioration in quality due to 'noise' in the copier process. Nucleic acids obey this general law as the information they encode is degradable by errors in the copier machinery or by agents such as heat, radiation and mutagenic chemicals[2].

How important has noise been in evolution? The error frequency in DNA replication in modern eukaryotes is about one incorrect nucleotide incorporated for every 10^9–10^{11} bases polymerized during any one round of replication[3]. But studies on non-enzymatic synthesis in simulated prebiotic environments suggest that the error rate in the 'first' genes was of the order of 10^{-1}–10^{-2} substitutions per base per generation[4,5]. Thus as we go back in evolution the amount of noise in the genetic copier mechanism rises by a staggering factor of one hundred million or more.

The amount of information a self-reproducing system can stably maintain is inversely proportional to the error rate of the copier system[5]. Since the accepted mutation rate of enzymatically catalysed polynucleotide synthesis in the absence of repair is about 10^{-3}–10^{-4} (refs 5,6) one can predict that the maximum amount of information encodable in a single genetic molecule at this stage of evolution was of the order of 10^5 nucleotides[5] (in point of fact it was probably somewhat less because such a system could not correct errors introduced by external factors such as heat, radiation or *p*H). In this kind of situation selection would almost certainly favour systems with multiple copies of their genomes since redundancy makes it possible to mask the deleterious effects of harmful mutations by complementation[7]. Thus I believe we can be reasonably confident that early genetic systems were 'polyploid' in the sense that their genetic information was represented several times over. This contrasts sharply with the traditional view that early cells were haploid.

Self-replicating error-prone genomes are today found only in the RNA rivuses and of these only the retroviruses possess the genome redundancy postulated to have been a key feature of early genetic systems. Retroviruses are important however because they offer a significant contemporary insight into the influence of noise in evolution. Viruses of this group contain a reverse transcriptase enzyme which makes DNA on a RNA template. Reverse transcription is the only surviving mode of DNA synthesis which is about as error-prone as RNA synthesis[8]. On passing from single-stranded RNA (the free virus) to double-stranded DNA (the integrated nuclear copy) retrovirus information experiences a millionfold drop in noise levels (see the figure). When this information is transcribed back into RNA the error rate rises by a comparable factor because DNA-dependent RNA synthesis lacks corrective functions. It is difficult to believe that these passages between low- and high-fidelity copier systems have not affected the evolutionary success of retroviruses. When integrated into cellular DNA the viral genes can exploit the repair systems of their host chromosomes and thus maintain strict homogeneity of nucleotide sequence during copying. On re-entering an independent life, the virus can offer a spread of variant sequences (that is survival options) to the test of selection. Retroviruses have the best of both worlds.

The integrated genomes of retroviruses have some tantalizing similarities to certain families of repeated sequences in the mammalian genome such as the *Alu* family[9] and the genes encoding some small nuclear RNAs[9,10]. Thus it is not surprising that these families show evidence of having passed through a RNA phase followed by reverse transcription and re-integration into chromosomal DNA[9,10]. The same seems to be true of 'pseudogenes' — partial duplicates of structural genes, many of which lack introns, have a 3′ poly(A) 'tail' and generally resemble mRNAs that have been reverse-transcribed back into DNA. The discovery of pseudogenes for mouse α-globin, human κ immunoglobulin, human β-tubulin, human metallothionein and rat α-tubulin[9] suggests that potentially any sequence in a higher-cell genome can pass through a RNA → DNA pathway. Reverse transcription thus closes the flow of information in higher cells into a loop which causes genes to alternate between low- and high-error copying systems.

Could such a cycling of information make a significant contribution to evolution? In assessing this question it is important to recognize the amount of RNA variation that is available. Since transcriptional copying in modern cells retains the high error rate (10^{-3}–10^{-4}) characteristic of uncorrected nucleic acid synthesis (Fig. 1) most transcripts of nuclear genes may contain at least one error. The amount of sequence polymorphism present may be magnified by the ability of the RNA processing mechanism to direct appropriately miscopied RNAs into a variety of alternative splicing pathways[11]. Given that a single gene in a differentiated cell may generate 50,000 copies of its cognate mRNA[12] it follows that the population of RNA molecules in a clone of cells can experience in a matter of months a degree of sequence variation which their DNA genome in the absence of selection might take hundreds of thousands of years to achieve. The key question is whether such variations can find their way back into the genome?

Two known mechanisms are available. A processed gene may 'donate' its RNA-based mutations to its parent gene by gene conversion, a process which seems to take place rather frequently in higher cell genomes[13]. Indeed, if a cDNA reverse-transcribed from mRNA were matched against its original gene, then conversion in one direction could imprint the restructured intron-deficient or intron-lacking sequence into its genomic homologue while leaving the promotor signals intact. This would allow processed information to feed back into the genome in functional form. It is also possible that RNA molecules transcribed from transposon-like elements may be reverse-transcribed into a heterogeneous pool of 'nomadic' plasmid-like DNA rings as has been observed in the case of the *Alu* family of sequences[14]. These DNA rings would be potentially genetically transmissible through the germline in a non-mendelian fashion without necessarily integrating into chromosomal DNA. Thus cells clonally derived from a common ancestor may become polymorphic in those molecules which have passed through an RNA phase while retaining rigorous sequence identity in the original DNA genes. In this way new adaptive possibilities could be canvassed without erasing the existing phenotype.

Given that effective mechanisms for promoting the RNA-to-DNA pathway exist it is more difficult to assess how often this route of information transfer has been used in evolution. It has been suggested that perhaps 20 per cent of the mammalian genome originated as RNA that was written back into DNA[10]. In many systems the figure may be higher. If one assumes that pseudogenes with 15–30 per cent divergence have been seen or inferred for 10 per cent of genes one can say there has been a reintegration event in the germline for about 10 per cent of genes within the last 10–20 million years. This corresponds to about 0.5 per cent to 1 per cent of genes per million years or once for each gene every 100–200 million years. On the other hand it must be admitted that there is no hard evidence that any functional eukaryotic genes are derived from reintegrated mRNAs since known higher-cell genes (with the exception of the α and β interferons and the histones) contain introns. To date the most likely candidate for a one-way gene conversion event is the rat insulin gene which has two alleles, one of which contains two introns while the other contains only one[10].

While there is no evidence for active 're-integrated' genes in eukaryotes it seems likely that the passage of information through the DNA → RNA → DNA loop has been a factor in the modular evolution

© 1984 Macmillan Journals Ltd

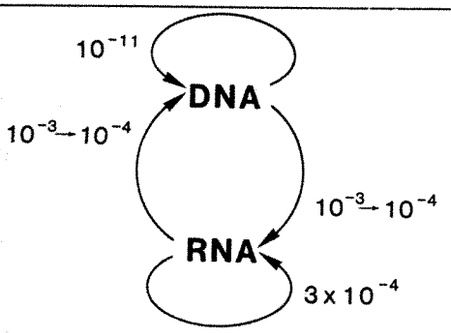

Fig. 1 Information cycles in genetic systems. The error-prone DNA → RNA step occurs at high levels in active cells during the normal course of protein synthesis. The error-prone RNA → DNA step occurs as an essential part of the life cycle of retroviruses. There is now good evidence that cellular sequences may also follow this pathway on occasions. If one assumes that pseudogenes with 15–30 per cent divergence exist for about 10 per cent of genes one can estimate that reverse transcription of a cellular sequence followed by re-integration occurs in the germ line once for each gene every 100–200 million years. This is slow but significant on the evolutionary time scale. The actual rate may of course be much higher.

of split genes. Blake and others have suggested that exons correspond to discrete peptide substructures which often have specific functions[15,16]. Each time a mosaic gene (in whole or part) cycles through an RNA intermediate back into the genome, intron removal knits the exons together into more complicated structures. Such multi-exon aggregates would normally be inactive but they could regain activity by conversion, or by incorporation into other transcriptional units followed by mutation. Such processes would, over evolutionary time, increase the complexity of protein structure by building more and more functional capacities into the one polypeptide. On this basis older genes would consist of very short exons embedded in an excess of 'junk' while modern genes would contain fewer introns and more complex exons.

Many contemporary genes bear the stamp of this kind of process. According to Gō, the globin gene, which has two introns, is made up of four peptide modules, not three (see ref. 17). Gō believes the now contiguous central coding region of the gene was once split by an intron[17] which has since been precisely removed, presumably by passing through an RNA processing stage. Similar processes seem to have occurred in the genes for egg white lysozyme and cytochrome *c*[17]. The end products of this bit-by-bit process of protein evolution are the uninterrupted genes of prokaryotes, where, according to Doolittle[18] and others, all introns have been removed in the interests of efficiency and economy.

Apart from its possible relevance to protein evolution the ability of nuclear information to occasionally pass through a noisy RNA copier has implications for students of evolution who seek to estimate times of (recent) evolutionary divergence by comparing the base sequence of an intron-lacking pseudogene with that of its intron-plus parent (see for example ref. 19). Such calculations should be tempered by the knowledge that a molecular clock based on RNA runs at a much faster rate than one based on DNA.

While DNA is a high-fidelity copier system this very stability may deny it a preponderant role in short-term adaptation. By contrast the noisiness which makes RNA a genetic liability (where 'large' genomes are concerned) also makes it an ideal channel for the controlled introduction of novelty. In a limited but important sense then DNA may be regarded as the guardian and RNA the modifier of genetic identity. By switching back and forth between these extreme levels of noise evolution may have struck an effective balance between conservatism and change. □

Cell patterning

Plants under strain

from Clive Lloyd

BEING nasty to your houseplant might put it under strain but, for a plant developmental biologist, the word strain takes on a different meaning: it denotes those tensions, propagated across cells and tissues, that have been hypothesized to orientate the insertion of new cross-walls, and so play a part in cell patterning. Scientists have been trying for some time to come to terms with the forces that influence the partitioning of cells in tissues. Observation of groups of cells can persuade that purely physical rules are involved and nineteenth century scientists (and, later D'Arcy Thompson) compared the behaviour of young cross-walls, of which no more than three walls are seen to meet at one point, to liquid films. But bricks, rather than bubbles, provided the analogy for Sinnott and Bloch's pioneering work in the 1940s.

They noted that when a new cross-wall formed in one file of cells, it avoided lining up with a cross-wall in the neighbouring file — much as bricks are staggered between courses in a wall. However, they also recorded that there was no such avoidance in cells induced to divide by wounding; thereby illustrating that previously formulated 'rules' are frequently broken[1,2] because the quality of the response seems to be affected by local conditions. Other examples of 'rule breaking' appeared. New cell walls may initially be formed parallel to the sides of the mother cell but, upon further centrifugal development, the growing cell plate can swerve towards one side, producing a smaller wedge-shaped cell — from a purely physical analogy it could be argued that the new cross-wall should be of the minimum surface area required to divide the cell.

The lasting contribution that Sinnott and Bloch[3] made to plant histogenesis was to emphasize that in vacuolate cells, a plate of cytoplasmic strands becomes positioned across the vacuole, with the ends of the strand attached to the mother cell walls along the line where the new cell plate will join them, before even mitosis has taken place. This structure, the phragmosome, can lay claim to the title of being the organelle least understood yet most likely to help our understanding of pattern formation — the task now being to find out more about its structure and about the forces that orientate it.

Forces that orientate the new cell plate are the subject of a letter in today's *Nature* by Lintilhac and Vesecky (see p.363). The point they make is that extracellular mechanical cues are sensed by cells in tissues and the new cell plate is orientated so that it is maximally protected from shear. Lintilhac and Vesecky studied tobacco pith, which, when taken into culture, grows into a disorganized callus. They attempted to re-establish ordered patterns of division by compressing callus in a frame, on the grounds that the *in vivo* mechanical

0028-0836/84/040319-01$01.00

© 1984 Macmillan Journals Ltd

environment for growth has been lost and cannot be restored by hormonal manipulation alone. After five days under compression, co-planar divisions were found in sections of calli. Allowing for the difficulty of obtaining uniform results from such variable material as callus it is intriguing that compression can yield co-planar divisions up to a depth of ten ranks of cells.

The observation will add fuel to an idea expressed at different times in different ways (see, for example, refs 4–7) that the development of plant form involves epigenetic control over the alignment of cross-walls through a programme of division and expansion which imparts each cell with a different positional value that is 'read' in terms of strain alignment of the cell plate.

At the cellular level, however, it is still not understood how the cell plate is aligned. Vacuolate cells, stimulated to divide by wounding the tissue, possess a circumferential band of microtubules[8] whose orientation forecasts the plane of division in much the same way that the pre-prophase band of microtubules does in meristematic cells (for a review, see ref. 9). However, the question of whether the pre-prophase band is the result or the cause of cytoplasmic polarization remains unresolved, although recently published observations by Galatis *et al.*[10] throw interesting light upon it.

In the stomatal complex of *Triticum* leaves, two pre-prophase bands, rather than one, are sometimes formed simultaneously within a single long cell. Following mitosis, a cell plate is deposited which curves from one of the cortical zones, previously marked by a pre-prophase band, to the other. Again, this behaviour is contrary to the minimal surface area hypothesis for cytokinesis. It is not known whether such curved cell plates are orientated by chemical or mechanical signals, but the observation that pre-prophase and telophase nuclei form acute local extensions (which these investigators liken to the pulling of the nucleus) hints at mechanical involvement. Unfortunately, all we have at the moment is hints; physical connections between nucleus and cortical cytoplasm are not yet resolved in higher plants but, if real, may provide a fuller understanding of how the growth of plant cells is patterned. □

Astronomy

IRAS circular 6

The source name consists of four parts: (1) the letters 'IRAS' to indicate the origin; (2) the right ascension (RA) in hours and minutes, seconds omitted; (3) declination (Dec) in decimal degrees, multiplied by 10 and then truncated (thus +32° 42.3 becomes +327); (4) an appendix starting with 'P' and followed by the number of the circular; this appendix stresses that the data are preliminary. Position is given at Equinox 1950.0. The measurements were made between epochs 1983.1 and 1983.6. Sources labelled PO3 were published in IRAS circular no. 3 and are included for completeness.

Source IRAS	RA (1950) h min s	Dec (1950) deg arc min arc s	Identification	Flux density (Jy) 12 μm	25 μm	60 μm	100 μm

The complexity and stability of ecosystems

Stuart L. Pimm

Department of Zoology and Graduate Program in Ecology, University of Tennessee, Knoxville, Tennessee 37996, USA

Early studies suggested that simple ecosystems were less stable than complex ones, but later studies came to the opposite conclusion. Confusion arose because of the many different meanings of 'complexity' and 'stability'. Most of the possible questions about the relationship between stability–complexity have not been asked. Those that have yield a variety of answers.

ELTON[1] noted the dangers of human simplification of the natural environment if ecosystems become less stable as they become more simple. The consequence may be increasingly unstable populations leading to extinctions, further simplification and even more instability. That there might be a single relationship between such gross variables as stability and complexity is intriguing theoretically, in a field where generalizations are scarce. The evidence on this topic is controversial. Early theoretical studies were logically simplistic, if appealing, in suggesting that complex system were more stable. Later theoretical studies were more sophisticated and suggested exactly the opposite. Field studies are, superficially, ambiguous and contradictory. I shall try here to resolve some of this controversy by pointing to several different definitions of stability, of complexity and of various ecological variables of interest. Several score permutations of these definitions are possible and different ones will yield different results. The earlier theoretical treatments and field studies typically address different combinations from those of later studies; in the few cases where they treat the same combination, there is often good agreement. Most combinations, however, have not been explored and very few have been studied extensively by both theoreticians and field workers.

Early studies[1–4] argued that increased complexity enhanced ecosystem stability. This seemed so certain that the idea became a central feature of ecology texts. Watt[5] makes one of his core principles of ecology '... the accumulation of biological diversity ... promotes population stability'. Later studies[6–21] typically came to the opposite conclusion. To see why early confidence was misplaced is easy with hindsight. The first of Elton's six arguments was a theoretical one: simple population models are characterized by oscillations; more complex models were expected to fluctuate less. Another theoretical argument, that of MacArthur[2], was that the more pathways for energy to reach a consumer, the less severe would be the failure of any one pathway. Perhaps because it represents conventional wisdom ('don't put all your eggs in one basket'), the argument was not given a formal mathematical treatment. The conflict between this argument and the diametrically opposite one from later studies is one I shall try to resolve.

One of Elton's lines of evidence involved the increased chance of pest outbreaks in agricultural systems, another the absence of pest outbreaks in tropical (but not temperate) forests and the prevalence of population cycles in the Arctic and, finally, the ease with which species can invade small, remote (and hence species-poor) oceanic islands. Elton's data were few: the absence of pest outbreaks in the tropics was based on a casual conversation with three tropical foresters[1]. Furthermore, man's impacts on agricultural systems are many and varied: simplification may not be the only, or even the main cause of their instability.

Simply, the early theoretical arguments and field studies were heterogeneous and incomplete[22]. Yet this heterogeneity only points to the fact that there are many questions to be answered in the discussion of stability–complexity relationships. No single question has logical supremacy.

Definitions

Table 1 lists definitions I shall use to build an array of complexity–stability questions. This set of definitions is not exhaustive[23–26]; I have included those definitions that have been most studied or which promise to be amenable to both theoretical and field studies. One can create 'complexity–stability' questions by taking the possible combinations of measures of complexity, stability and variables of interest. Looking at all the possible combinations suggests some features that should be discussed before answers are sought.

(1) The definitions of stability imply different kinds of comparisons. If a system is not stable (in the strict sense of Table 1), we will probably not observe it except in transition to a new equilibrium[27]. Rather special dynamics are required to permit

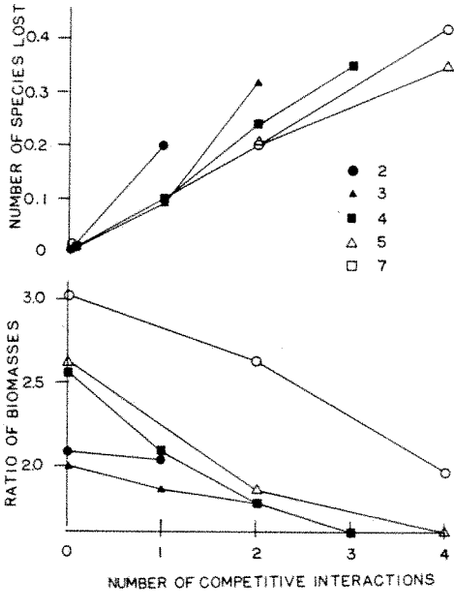

Fig. 1 An illustration of the diametrically opposite effects of increasing complexity on two different measures of stability. Results are from model systems where the single herbivore is removed from a system of possibly competing plants. As the number of competitive interactions between plants increases (abscissa), the system is more likely to lose plant species (upper graph) but change biomass less (lower graph) when the herbivore is removed. In the lower graph, the ratio of biomass plotted is the total biomass of plants without herbivore/total biomass of plants with herbivore. Numbers indicate numbers of plant species in the system.

Table 1 Definitions of variables

Complexity	
Species richness	The no. of species in a system.
Connectance	The no. of actual interspecific interactions divided by the number of possible interspecific interactions.
Interaction strength	The mean magnitude of interspecific interaction: the size of the effect of one species' density on the growth rate of another species.
Evenness	The second moment (variance) of the species abundance distribution measures how uneven are the abundances. (Diversity indices are measures that combine the evenness of the species' abundances (equitability) and species richness. The relative weighting of these two components varies from index to index. One member of this family is the information theoretic index, *H*.)
Stability	
Stable (units nondimensional and binary: 0 unstable, 1 stable)	A system is deemed stable if and only if the variables all return to the initial equilibrium following their being perturbed from it. A system is locally stable if this return is known to apply only certainly for small perturbations and globally stable if the system returns from all possible perturbations. The set of all values of the variables from which the system returns to a particular equilibrium is known as the domain of attraction.
Resilience (units of time; characteristic return time is time taken for a perturbation to return to 1/e (~37%) of initial value.)	How fast the variables return towards their equilibrium following a perturbation. Resilience is not, therefore, defined for unstable systems.
Persistence (units of time)	The time a variable lasts before it is changed to a new value. Turnover is the reciprocal of persistence.
Resistance (units nondimensional and continuous)	The degree to which a variable is changed, following a perturbation.
Variability (the units are those of animals squared per unit area (variance), animals per unit area (s.d.) dimensionless (c.v.)	The variance of population densities over time, or allied measures such as the standard deviation of population densities, or the coefficient of variation (standard deviation divided by the mean density c.v.).
Variables of interest	
Individual species abundances	The densities of all the species in the system.
Species composition	The list of all the species in the system.
Trophic level abundance	The total density (or biomass) of all the species in a particular trophic level (or for comparable definitions, for some other interesting set of species).

species to persist with population densities which do not return to an equilibrium, but instead, cycle indefinitely. Such dynamics are theoretically fascinating but seem to characterize only a few populations[28], such as lemmings and lynx. Thus, when we investigate the chances of stability of systems with different complexities we are implicitly comparing existing with hypothetical systems. For the other measures of stability, however, we could ask whether existing systems are more or less resilient, resistant, persistent or variable. (Although if they are not resilient, resistant or persistent enough or too variable, then, indeed, we may not observe them for long.)

(2) There are many kinds of perturbations to natural systems. Detailed answers to specific complexity–stability questions may depend on what is perturbed, when, and by how much. Some perturbations may involve changes in species abundances (like the English winter of 1962–63 which temporarily depressed bird populations[29]); others may involve the removal of some or all of the species (as in secondary plant succession) and thus involve recoveries of a much longer duration. Consequently, the definitions of resilience, persistence and resistance pose problems of scale when we attempt to measure them in the field[30]. It is obvious that large perturbations will disappear more slowly than small ones. The time taken for a perturbation to diminish to a given percentage of its initial value, however, may be relatively independent of the size of the perturbation. Such a statistic thus avoids the complication of the initial size of the perturbation, which will depend not only on the size of the disturbance but also on the system's resistance. The notion of persistence is more difficult to deal with. How long a system persists will not only depend on the system, but also on the properties of the disturbances. Defining comparable disturbances for different systems may often be difficult or impossible. But for some cases to be discussed, the differences in persistence clearly can be seen to depend on the intrinsic differences between systems and not on the disturbances.

It is also obvious that long-lived organisms (say, trees) will be less resilient and more persistent in numbers than short-lived organisms (say, annual plants) on a time scale measured in years[30]. Why some systems are dominated by organisms with short or long life histories may be the answer to some questions about resilience and resistence. For others, we may wish to scale resilience or persistence further by correcting for the generation times of the species involved.

Perturbations also need to be defined spatially. Disturbing 1 m^2 is not merely a smaller perturbation than disturbing 1 km^2: in the latter, the boundary is smaller relative to the total area, so immigration and emigration are likely to be relatively less important than birth and death processes.

In short, because of the problems of spatial and temporal scales, it may be impossible to compare widely different ecosystems. Yet for similar systems, contrasts of resilience, resistance, persistence and variability should be possible. Indeed, the field studies I shall discuss confirm this.

(3) The definitions of stability are interrelated in complicated ways. Under some circumstances, resistant systems, because they change less under a given disturbance, will appear more persistent and less variable. For some populations, increasing resilience implies decreasing variability[29] and, as discussed above, resilience and resistance may or may not be confounded depending on how the former is scaled. I shall not discuss these relationships, in part because Harrison[26] has already done so. However, the principal reason is that despite the potential for the reverse, theoretical and even field results fall cleanly into the various definitions of stability; and even if the correlation between any two definitions is absolute, we will retain both when, under different circumstances, each variable becomes an

Table 2 Theoretical and field studies on various combinations of measures of complexity, variables of interest and measures of stability

		THEORETICAL STUDIES		FIELD STUDIES	
		SPECIES RICHNESS	CONNECTANCE AND INTERACATION STRENGTH	SPECIES RICHNESS	CONNECTANCE AND INTERACTION STRENGTH
Individual species abundances	STABLE	Local stability: with more species there is less chance of stability[6-21] Modifications: (1) feasibility[32] (2) structure[10,11,31] (3) parameters[10,11] (4) donor-control[10] (5) succession, deletion and evolution[33-36] (6) predator foraging patterns[42,43]	Local stability: with more connectance and and greater interaction there is less chance of stability[6-9]	1) Cn ≤ constant[44-46]	2) Food webs lack links that are particularly destabilizing[27]. 3) Insect systems are more connected than vertebrate dominated ones[50]
	RESILIENT	With more trophic levels there is less resilience[53,54]	With more connectance there is greater resilience[11,27]	With more species there is less resilience[55]	
	PERSISTENT	1) Systems with more species are harder to invade[36,56] 2) With more species, it is less likely an invader will be a new species	With more interaction systems are harder to invade[56,57]	1) Successions: older, systems with more species are more persistent[58] 2) Islands: those with fewer species are easier to invade[1,59,60]	
	RESISTANT				
Species composition	STABLE	Species deletion: with more species there is less chance of stability (except for donor-control where the reverse is true[38,61])	Species deletion: with more connectance there is less chance of stability (except for donor-control where the reverse is true[38,61])	Indirect evidence: most systems are changed considerably by predator removals and are thus not donor-controlled[38]	
	RESILIENT				
	PERSISTENT			Geologically, systems with more species persist less[63]	
	RESISTANT

	RESISTANT	With more species, there is usually less resistance[66]	With more connectance there is more resistance[66]		

easier or more appropriate measurement of stability.

(4) The variables of interest are hierarchial in nature. If individual species abundances are maintained, then so are the number of species in the system, species composition and the total density or biomass of any subset of species. Yet species composition may remain the same while the densities of the species change, or vice versa.

(5) Connectance and interaction strength are closely related: their product measures how strongly all the species in the system interact. Theoretically, it is convenient to distinguish species pairs that interact from those that do not. Practically, we might expect a continuous gradation of interaction strengths from the strong to the weak and for these two measures to affect stability in comparable ways.

Table 2 compiles theoretical and field studies on some of the combinations of measures of complexity, variables of interest and measures of stability. Later, I shall discuss evenness as a measure of complexity and variability as a measure of stability. I shall first summarize what results are available, then conclude by pointing to some questions which appear experimentally and theoretically tractable and yet which do not appear to have been answered.

Individual species abundances

Stability. The majority of theoretical studies have examined local stability of species abundances. Initial results[6-9] found that increasing species richness, connectance or interaction strength decrease the chance that randomly assembled communities would be stable. Random assembly is an unreasonable assumption and other studies relaxed the assumptions on the structure and limits of the interaction parameters[10,11,31,32]. In addition,

models were allowed to develop through the successive additions or deletions of species[33–36].

The many subtleties to this work are reviewed by May[37], McDonald[13] and Pimm[27] and one feature seems capable of completely reversing the original result. In most models, increasing the density of the predator, decreases the population growth rate of the prey. Alternatively, predators may consume prey that are likely to die or have died from other causes—disease or starvation, for example. For these donor-controlled models, increasing connectance and species richness increases the chances of finding a locally stable model[10]. This result matches MacArthur's[2] idea that complexity buffers the consequences of density variations in one prey species. His argument is, however, incomplete: it fails to consider the variations in densities of species at higher trophic levels. For these, the opposite is true: variations propagate more widely the more connected the system. It is this latter effect that predominates in many models but, by definition, is absent in donor-controlled models. Donor-control dynamics predict that predator removal should have no effect on prey species densities and certainly not on the resultant community's species composition. Usually this is not the case[38]. With the rejection of donor-control dynamics goes one plausible model where increased stability comes from increased complexity.

In Lotka–Volterra models, resource limitation of species at the base of the food web helps to stabilize the system, and predator effects on prey density (absent in donor-controlled models) are destabilizing. However, the predator interactions, themselves, can be stabilizing. Typical examples of this involve some mechanisms for the prey to escape predation at low densities. Here, predators might not be able physically to attack the prey because the latter are hiding or, perhaps, because low densities cannot be profitably exploited. In these models there can be stable interactions with prey depressed to levels far below those set by resource limitation. Detailed case histories[39], general arguments about the structure of herbivore communities[40], or about herbivores in general[41] all suggest that many species may be limited primarily by predators rather than resources. For such cases Nunney[42] showed that increasing complexity and species richness could lead to an increased chance of local stability. The generality of Nunney's arguments have been questioned[43] but they also require the product of connectance (C) and species richness (n) to be sufficiently large ($Cn > 6$) to reverse the usual decrease in stability. I shall return to this point presently.

Is there any field evidence for these theoretical results? As argued above, the nature of the definition of local stability makes it unlikely (though not impossible) that we will observe anything other than locally stable systems. Many models suggest that, if interaction strength (i) is assumed to be relatively constant, then C should vary with $1/n$ in order to maintain local stability. Data from published food webs[27,44] or from more detailed studies of lizard communities[45] show that C does decrease linearly with $1/n$ or nearly so[46] with $Cn = 3$–4. These values, incidentally, seem too low for Nunney's argument, in the previous paragraph, to hold. Unfortunately, these results say nothing more than that each species interacts with a fixed number of other species as n increases—a result that seems reasonable without recourse to stability explanations[47]. There are, however, certain other patterns of species interactions (particularly those that involve species feeding on more than one trophic level[48], and the grouping of species interactions within a community[49]) that are particularly destabilizing in models. Natural systems show a statistical scarcity of these patterns[49,50]. Although interaction strength is hard to measure, it is likely to be less between an insect and its comparably sized insect parasitoid than between a large vertebrate predator and its small prey. Thus, stability should permit insect–parasitoid systems to be substantially more connected than vertebrate-dominated systems[48]. They are[50]. (With the exception just noted, most multi-species models do not consider parasitoid or parasite systems. Yet their distinctive features[51] and ecological importance[52], plus their greater potential complexity, suggest that other results from local stability analyses may not be simply transferable to them.)

In sum, most theoretical studies of local stability are best interpreted by saying that the systems we observe should not be too complex. Field evidence suggests this is correct; indeed, patterns of species interactions that are particularly destabilizing in models are also rare in nature.

Resilience. In models, systems with more trophic levels (one way of adding species) are less resilient[53,54] and, for a given number of trophic levels, stable systems will often[11,27], but not always[43], be more resilient the more complex they are. Resilience is amenable to field determination[29] and unlike stability, permits comparisons of existing natural systems. However, I know of only one such study[55]. It found that plants in a species-poor system recovered more quickly from an unusual drought than those in a nearby species-rich field.

Persistence. How long should species densities continue to return to a given equilibrium and not to some other equilibrium involving the same or some different set of species? One long-term question is whether constantly simple systems persist longer than complex ones (for example, are the species abundances of species-poor desert communities more persistent than those of species-rich tropical forests?). I shall consider this topic below. A second, relatively short-term view, posits changes in both composition and individual abundances, effected, perhaps, by the addition of a species to the system. This presumes that the community has fewer species than the set of those capable of reaching the community (this set is called the species pool). This topic is particularly relevant to islands (either typically oceanic ones or abstract islands of isolated habitat which may lack a full complement of species) or communities which, following a major disturbance, may also lack species.

How hard are communities to invade? Those that are hard to invade will be persistent and vice versa. Models that examine species competing for resources arranged along some gradient[56] and more general models of food web assembly[36,57] suggest that communities with more species are harder to invade. In addition, the smaller the fraction of the species pool present in a community, the more likely an invading individual will be of a new species. The more new species that invade per unit time, the more likely it is that one of them will be able to increase and so change the existing system's equilibrium. Simply, both effects mean that the fewer the species in the system, the less persistent that system will be. The effect of increased interaction between species is also to increase persistence[56,57].

There are two kinds of field evidence for these effects. First, during succession, species that enter the community later (when there are usually more species) persist longer than those that enter earlier[58]. In part, this must be due to longer-lived organisms arriving later. The question of whether later-arriving organisms persist longer relative to their generation times has not been asked. Of course, that longer-lived organisms arrive later may simply be a reflection of the greater likely persistence of later successional stages. The second evidence avoids these difficulties, for even among species with similar generation times, species are more likely to colonize remote, species-poor islands successfully than species-rich continents[1,59,60].

Species composition

Stability. If individual species abundances remain fixed, then so does species composition; thus, much of the previous section applies to this one. It remains to ask, under what conditions does species composition remain unchanged, even though individual abundances change considerably? There are two kinds of studies. The first kind considers the effect of removing species on the composition of the remaining species ('species deletion stability'). Other studies consider whether, following changes in density, species abundances will return to their original equilibrium or move to some new equilbrium involving different abundances but the same composition.

Theoretically, species deletion stability decreases with increasing numbers of species and connectance[61], but it also depends

critically on which species are selected for removal[38]. If model plants are removed, more species and greater connectance will lead to a lessened chance of losing more species: these results confirm MacArthur's[2] intuition. For model predators, however, the result is reversed. Of course, donor-controlled systems are not affected by predator removals and, for these, more complex systems will be more species deletion stable[38]. As noted above, donor-controlled dynamics do not predominate in nature[38].

A second problem involves populations which appear to continue at one level for years, then shift to another one and remain there. Lotka–Volterra models do not have this property—more complex dynamics with more parameters are required[62]. In this special sense, systems with greater (dynamic) complexity may permit species composition to remain unchanged when comparable simple models would predict species losses.

Resilience. How fast species composition returns to equilibrium following, say, a major reduction in species, is a question central to the topic of ecological succession. Data are certainly available on how fast succession proceeds. However, I know of no synthesis that relates the rate at which disturbed systems approach their former composition to the various definitions of complexity.

Persistence. I have already noted that species composition should and does last longer when more species are present—at least when viewing the process of succession. But what about the non-successional differences among systems, the species richness of forests versus deserts, for example? In the long term, we might expect development of better prey or predators and changing environmental conditions to cause species losses. From the results on species deletions, we might expect systems with more species to last for shorter periods. The relationship of the persistence of species composition to species richness, therefore, may be dependent on the timescale considered. Boucot[63] finds that for marine fossil assemblages 'trophically complex systems... are far more fragile and subject to extinctions' than simpler systems and, hence, tend to last for shorter periods. As E. R. Pianka has observed (personal communication), excepting succession, species compositions of many systems are persistent over at least human life spans.

Total density or biomass

The total density (or biomass) of all or some subset of the species in an ecosystem may correlate far more closely with our notions of what defines an ecosystem than the abundances or identities of particular species. For example, we readily recognize a deciduous forest. But consider, say, 1 km^2 plots of deciduous forest in eastern North America or western Europe. Within these plots there will be a wide range of tree species, an even greater variation in the abundance of individual tree species, but not, I suspect, a large variance in the total biomass of all tree species.

Resilience. Theoretically, densities of certain sets of species can be more resilient than those of their constituent species and, moreover, this resilience can increase with increasing connectance[64,65]. I know of no field study that relates biomass resilience during succession to complexity.

Resistance. There are both theoretical[66,67] and experimental[55,68,69] studies of the degree of change of biomass and density with the addition or removal of a species or resource. Two of these studies[66,69] focus on the effects of large mammalian grazers on plant biomass. Models with few plant species but more connectance (interactions between plants) have greater resistance[66]. The former result also holds for very complicated ecosystem models[67]. Greater evenness of prey abundances (a measure of complexity not yet discussed) correlates with greater resistance both theoretically[66] and in field studies of mammalian grazing[69].

Other variables

I have not discussed variability as a measure of stability because I believe there are difficulties in testing the various theoretical ideas. How much populations vary will depend not only on intrinsic factors involving ecosystem complexity[70–72], but on the extrinsic nature and frequency of the perturbations. In the species-rich tropics, populations do not vary less than in temperate systems[22,72,73]. Yet populations do vary more in climatically unpredictable systems than in predictable ones[73], suggesting that extrinsic factors may govern variability more than intrinsic ones.

Nor have I discussed pest outbreaks. While it may be that pest species are the most variable[74], it is more likely that they are simply those species whose densities are high relative to what humans require them to be. Pimental's[75] finding of lower densities of herbivorous insects with greater species richness might be explained by considerations of equilibrium densities rather than by the definitions of stability used here. The determinants of equilibrium densities[76] or human requirements[77] fall outside the scope of this review, but within its scope is the question of what determines how fast an insect population returns to an economically unacceptable equilibrium after being severely reduced by insecticides. I have already considered resilience a measure of stability. In contrast, for pest outbreaks, a resilient population might be considered unstable, while one that recovered slowly might be considered stable. Resilience might indicate stability or instability depending on one's viewpoint[78]. As noted above, with fewer species, resilience tends to increase: whether this is a general explanation of outbreaks is an intriguing possibility, but one clearly based on too few theoretical and field studies.

Conclusions

Theoretically, the more species that are present in a community: (1) the less connected it should be, if it is to be stable, (2) the less resilient will be its populations, (3) the greater will be the change in composition and in biomass when a species is removed, (4) the longer the persistence of species composition in the absence of a species removal. The more connected a community: (1) the fewer species it must have if it is to be stable, (2) the more likely it is to lose other species if one is removed, but (3) the more resilient will be its populations, (4) the more persistent will be its composition and (5) the more resistant will be its biomass if a species is removed. Clearly, different complexity–stability questions yield different answers (Fig. 1). The fact that they do, often explains some of the earlier controversy generated, it is now obvious, by different authors addressing different questions.

Which questions have not been examined? Local stability is a clearly defined concept mathematically and the majority of theoretical studies examine it, alone[26]. Field studies have not usually addressed local stability because, I suspect, it involves a comparison of existing and hypothetical systems. What field studies have examined are questions that permit comparisons of existing systems and which involve more general views of a system than individual species' abundances, How fast does species composition or total biomass return to equilibrium, how long does composition remain unchanged and how much is composition or total biomass changed following, say, the addition of a species? These questions are as theoretically tractable as those of local stability. Similarly, some accessible theoretical ideas—like resilience—are rarely measured in the field, despite the potential to do so. Put simply, progress in our understanding of the complexity and stability of ecosystems will come from more theoretical and field studies, but is likely to be fastest when these studies consider which questions are both theoretically tractable and experimentally testable: I suggest the many gaps in Table 2 provide a guide to what these questions are.

I thank R. A. Armstrong, J. H. Lawton, R. M. May, S. J. McNaughton and E. R. Pianka for comments on earlier versions of this paper. ARTICLES

The Hubble constant as derived from 21 cm linewidths

Allan Sandage & G. A. Tammann*

Mount Wilson and Las Campanas Observatories, Carnegie Institution of Washington, 813 Santa Barbara Street, Pasadena, California 91101, USA

The IR 21 cm linewidth–absolute magnitude relation is calibrated by means of local galaxies with known distances, including new distance determinations of M33 and M81. The calibrated relation is applied to 17 Virgo cluster galaxies of type Sab to Sd and yields a cluster modulus of $(m-M)^0_{Virgo} = 31.47 \pm 0.34$. *Reliable relative distance indicators are used to extend the distance scale to the Coma cluster, for which a distance modulus is found of* $(m-M)^0_{Coma} = 35.39 \pm 0.35$. *The blue 21 cm linewidth–absolute magnitude relation gives slightly larger distances. A combination of the two methods leads to a Hubble constant at the distance of the Coma cluster of* $H_0 = 55 \pm 9$ km s^{-1} Mpc^{-1}. *This value agrees with the global value of* $H_0 = 50 \pm 7$ km s^{-1} Mpc^{-1}, *giving a Hubble time of* $H_0^{-1} = 19.5 \times 10^3$ Myr, *in aggreement with the age of the chemical elements and with the age of our Galaxy, determined from globular clusters.*

In a recent discussion of the Tully–Fisher relation[1] it was stated that the extragalactic distance scale and the value of the Hubble constant depend now only on the infall velocity towards Virgo, and on the distances of the galaxies in the neighbourhood of the Milky Way. Because the former is now well determined from an accurate measurement of the relative distance between the Virgo and Coma clusters[2], and because new fundamental distances to two nearby calibrating galaxies, M33 and M81, have recently become available[3–5], it seems justified to look into the consequences of these new developments.

* Permanent address: Astronomisches Institut der Universität Basel, European Southern Observatory, Venusstrasse 7, CH-4102 Binningen, Switzerland.

The Tully–Fisher relation, that is the dependence of the luminosity of disk galaxies on their 21 cm linewidth, has been widely used to derive extragalactic distances, either by correlating the absorption-corrected blue B magnitude (ref. 6 and refs therein) or the nearly absorption-free IR H magnitude (ref. 1 and refs therein) of a disk galaxy with its inclination-corrected 21 cm linewidth Δv_{21}. So far the IR Tully–Fisher relation has consistently led to a surprisingly low Virgo cluster distance of only 16 Mpc, compared with 22 Mpc which follows from other distance indicators, which are insensitive to selection effects and statistical bias[7,8]. We investigate here this discrepancy, as well as the consequences for the Hubble constant H_0.

Data

We restrict the present sample to Sab to Sd spiral galaxies. Very late-type galaxies (Sdm, Sm, Im) are excluded, because knowledge of their intrinsic shape is inadequate to derive reliable inclination angles. Sa galaxies are excluded because there are reasons to doubt that they obey a Tully–Fisher relation; a complete sample of Sa galaxies with $i > 45°$ from the *Revised Shapley–Ames Catalog*[9] does not reveal a significant dependence of M_B on $\log \Delta v_{21}$. This lack of correlation is possibly related to the fact that Sa galaxies have rotation curves which rise steeply in the central regions. The maximum rotation velocity, v_{max}—which essentially determines the 21 cm linewidth—measures only the mass of the rotating bulge, which is a fraction of the total mass (and light) of an Sa galaxy[10].

A Tully–Fisher relation has the form

$$M_H = a - b\ (\log \Delta v_{21} - 2.5) \quad (1)$$

where M_H is the absolute galaxian magnitude in the H band. The constant term a can be determined from nearby calibrator galaxies with known distances (Table 1). The slope b is treated in a first step as a free parameter with values of $b = 10$–13. The best value of b will be discussed later.

Table 1 contains all spiral galaxies for which fundamental distances are available from Cepheids and/or brightest stars and other distance indicators. The Cepheid distances were not increased by a bulk correction of ~0.3 mag, which in the past has seemed to be required by the increased Hyades cluster distance. This open cluster, often used to fix the zero point of the Cepheid period–luminosity function, was originally assigned a distance modulus of $(m-M)^0 = 3.03$, whereas a value of 3.30 seems now much more probable. This change, however, enters with very little weight into the zero point determination of the period–luminosity relation for reasons discussed elsewhere[3]. Briefly, the zero point from Cepheid radius determinations agrees well with our old zero point without the Hyades increase, and an increase of the Magellanic Cloud moduli by 0.3 mag would conflict with their RR Lyrae star moduli. It seems therefore that our original main-sequence fitting was slightly in error, but that error has just been compensated by the increased Hyades modulus, leaving our first Cepheid zero point[11,12] nearly unchanged. This now seems to be established via the open cluster NGC6087 which contains the Cepheid S Nor, on the basis of new observations by J. W. Pel (personal communication).

** Assumed to be at the same distance as M101; compare refs 30, 31.

Two distances in Table 1 need special comment: the distances to M33 and to M81. (1) The distance of M33 (NGC598) has only now been firmly based on Cepheids[4,5]. Its true distance modulus of $(m-M)^0 = 25.33$ (1.1 Mpc) makes it 1.6 times more distant than M31, provided the distance of the latter galaxy is correct. It has been suggested on the basis of IR photometry of the Cepheids in M31, that the true distance modulus of this galaxy is $(m-M)^0 = 24.6$ (ref. 13), which would reduce the distance ratio of M33 and M31 to 1.3. The increased distance to M31 has conservatively not yet been considered here. (2) Lacking a direct distance determination to M81, it has previously been assumed that M81 lies at the same distance as NGC2403. However, recent measurements of the Cepheids, of the colour-magnitude diagram of the brightest blue and red stars, and of the novae in M81 (ref. 5) leads to an apparent blue modulus of $(m-M)^{M81}_{AB} = 28.8$ which is 1.0 mag larger than adopted previously, based as it was then on the modulus of NGC2403. We should also point out that the distance to NGC2403 adopted in Table 1 may again be conservative, because IR photometry of the Cepheids in that galaxy suggests a true distance modulus of $(m-M)^0 = 28.15$ (ref. 14).

As in the case of the M81 group, it appears now as an oversimplification to assume the 'members' of the South Polar Group to lie at a common distance[9,15]. In the latter group a reliable Cepheid distance is only available for NGC300[16]. NGC55 seems to lie at approximately the same distance, judging from its resolution into stars. Unfortunately no H magnitudes are available for these two galaxies; the values in Table 1 were calculated on the assumption that the intrinsic colour of an Sc galaxy is $(B-H) = 1.4$. NGC253 and NGC7793 are judged to be 1 mag more distant on the basis of their resolution into stars, and the same criterion suggests that NGC247 lies between the pairs NGC300/55 and NGC253/7793. These distances are quite tentative, and they are given only half weight in Table 1. NGC300 and NGC55 are also given half weight because of their somewhat uncertain H magnitudes. The IR $H^c_{-0.5}$ magnitudes, corrected for absorption, were taken from refs 17 and 19. The 21 cm linewidths were averaged from refs 6, 17 and 19. The Tully–Fisher relation of the calibrators is plotted in Fig. 1.

Values of the constant term a of equation (1), as determined by the calibrator galaxies, are listed in Table 2 for different values of the slope b. The first set of solutions for a is based on the six calibrator galaxies with full weight in Table 1; the second set of solutions uses all 11 calibrators with the appropriate weights given in Table 1. Comparison of the two sets shows that the value of a is quite insensitive to whether or not the traditional South Polar Group is excluded. For the following discussion the solution adopted is based on only six calibrators.

Table 3 lists all Shapley–Ames galaxies within 6° of the Virgo cluster centre[9] with known IR magnitudes $J^c_{-0.5}$ (refs 17, 18) and 21 cm linewidths[6,18]. Two galaxies, NGC4206 and NGC4498, for which the necessary data are available, were added. The sample is the same as that considered in refs 1 and 18, with the exception that Sa and very late-type galaxies are excluded here. The Tully–Fisher relation of the Virgo galaxies is shown in Fig. 1.

Distance of the Virgo cluster

The open symbols denote low-weight galaxies. The lines in the two diagrams have the adopted slope $b = 11.5$.

galaxies in Table 3 can be calculated. The resulting mean distance moduli for different adopted values of b are listed in Table 2, as well as the mean standard deviation of that mean. An important conclusion is that the Virgo modulus depends on the value of b, varying from $(m-M)^0_{\text{Virgo}} = 31.34$ for $b = 10$ to $(m-M)^0_{\text{Virgo}} = 31.60$ for $b = 13$. The slope dependence becomes even stronger if the traditional South Polar Group is included among the calibrators. Following ref. 18 the interacting galaxy NGC4438 and the deviating galaxy NGC4569 are excluded here, and NGC4519 and NGC4535 with uncertain inclinations are given half weight. In view of the slope dependence it is important to determine the best value of the slope b. The six calibrating galaxies in Table 1 give very uncertain values of $b = 9.4$ or $b = 10.0$, depending on whether $\log \Delta v_{21}$ or M_H are treated as the independent variable. In the case of the Virgo galaxies the errors should lie mainly in the Δv_{21} values; hence treating M_H as an independent variable yields $b = 10.5$; this value is again quite uncertain and is sensitive to the weight given to individual galaxies. We therefore adopt the value of $b = 11.5$, which was derived for 300 field galaxies of different types, making allowance for a Virgo-centric infall model[1]. With this slope, the r.m.s. scatter of the present Virgo sample becomes $\sigma = 0.53$ mag.

From interpolation in Table 2 one finds for $b = 11.5$ a Virgo modulus of

$$(m-M)^0_{\text{Virgo}} = 31.47 \pm 0.34 \qquad (2)$$

corresponding to a distance of 19.7 ± 3.1 Mpc. Here the mean standard deviation includes the uncertainty of a, but it does not include a remaining systematic error of ± 0.15 mag due to the uncertainty of the slope b.

$(m-M)^0_{\text{Coma-Virgo}}$	3.92 ± 0.09	

Value of H_o

The distance of the Virgo cluster combined with its mean recession velocity leads to an unreliable value of the Hubble constant, because the observed recession velocity is affected by streaming motions within the Virgo complex and possibly, although to a lesser extent, by the random peculiar motion of the Local Group. Present determinations of the streaming velocities show them to be of the order of 20% of the Virgo cluster velocity (refs 7, 20 and refs therein).

At the distance of the Coma cluster with a mean recession velocity of almost 7,000 km s^{-1} any non-Hubble velocity component can hardly amount to as much as 10%, because it is known from the cosmic microwave background that the largest peculiar motion we partake of is ~600 km s^{-1}.

Fortunately the relative distance between the Virgo cluster and the Coma cluster is now determined with exceptional precision from different (relative) distance indicators. The available determinations are listed in Table 4 and yield a mean modulus difference of $\Delta(m-M)_{\text{Coma-Virgo}} = 3.92 \pm 0.09$, The IR colour–luminosity relation of E galaxies, which give decreasing distance differences with increasing wavelengths[21], have not been considered here, because these colours must either mean that the E galaxies in Virgo and Coma have different IR properties, or they reflect remaining observational difficulties. Indeed, the IR colours are not true simultaneous colour observations, but are the difference of magnitude observations taken by different observers at different telescopes and reduced to a common blue isophote.

The Virgo cluster distance in the previous section combined with the modulus difference from Table 4 gives a Coma modulus of

$$(m-M)_{\text{Coma}} = 35.39 \pm 0.35 \qquad (3)$$

corresponding to a distance of $r = 120 \pm 20$ Mpc. The mean Coma cluster velocity, corrected by $300 \sin l \cos b$ km s^{-1}, is $v_o = 6{,}952 \pm 61$ km s^{-1} (ref. 22) or with our preferred correction to the centroid of the Local Group[23], $6{,}913 \pm 61$ km s^{-1}. From this follows

$$H_0 = \frac{v_0}{r} = 58 \pm 10 \quad \text{km s}^{-1}\,\text{Mpc}^{-1} \qquad (4)$$

Discussion

We have followed the prescriptions given in refs 1 and 18 for the application of the IR magnitude–21 cm linewidth relation, and have shown that the value of the Virgo cluster modulus via the Tully–Fisher route does depend on the adopted slope b. Using the Aaronson–Mould best value of b, we obtain a modulus of 31.47 ± 0.34. Although we believe there are difficulties in the Tully–Fisher method when it is pushed to obtain $\pm 20\%$ accuracies, the purpose of this article is to point out that using the prescriptions advocated in ref. 1, we nearly reproduce the preferred value of $m - M = 31.7$ obtained by other methods[7]. The modulus increase over the Aaronson–Mould value of 31.08 ± 0.11 is due almost entirely to two causes: (1) The new fundamental distances of M33 and M81 have changed the constant term a in equation (1) from $a = -21.39 \pm 0.11$ (ref. 1) to $\sim -21.6 \pm 0.3$ (depending on the adopted slope). The change is not larger, because we have not applied the bulk correction to the calibrating galaxies for the increased Hyades modulus. (2) Aaronson and Mould[1] have adopted a slope of $b = 10$, although

their preferred solution gives a slope of $b = 11.54$. They argue that the choice of the slope has negligible effect on the distance modulus, but as shown in Table 2 their steeper slope makes a difference of $\Delta(m-M) = +0.13$. The sensitivity of the solution to the slope has also been emphasized by Richter and Huchtmeier[6]. (Aaronson and Mould[1] have not included in the quoted error their estimated zero point error of 0.2 mag; with this additional error included our error estimates do not deviate significantly.)

In an investigation of the slope of the blue Tully–Fisher relation, Richter and Huchtmeier[6] have found a slope of $b = 7.17$ and from a large sample of 66 Virgo galaxies a Virgo cluster modulus of $(m-M)_{\text{Virgo}} = 31.82 \pm 0.14$. Adopting their slope, using the local calibrators as shown in Table 1, and including only the 48 Virgo galaxies of type Sab to Sd of their sample, we find $(m-M)_{\text{Virgo}} = 31.66 \pm 0.26$ (the error here includes the error of the constant term $a = -19.82 \pm 0.23$).

It is reassuring for the 21 cm linewidth method, that it yields Virgo cluster distances for IR and blue magnitudes that are almost the same. The mean value of $(m-M)_{\text{Virgo}} = 31.57 \pm 0.25$ agrees well with our independently determined value $(m-M)_{\text{Virgo}} = 31.67 \pm 0.26$ (ref. 7), but we emphasize that the 21 cm method should be viewed with caution until it is better understood why the Hubble-type dependence has not yet been found in the radio data, but is clearly present in the optical results[10]. If one carries the distance scale beyond the Virgo cluster out to the Coma cluster by means of relative distance indicators given in Table 4, one obtains a value of the Hubble constant which must essentially be free of all irregularities of the expansion field and thus must be very close to the global value of H_0. Adopting a Virgo modulus based on the IR Tully–Fisher relation leads then to $H_0 = 58 \pm 10$, or $H_0 = 55 \pm 9$ on the basis of the IR and blue Virgo modulus. Both solutions lie well within the error range of the preferred value of $H_0 = 50 \pm 7$ (ref. 7).

There are remaining problems with the Tully–Fisher relation. In addition to the problem of the dependence on galactic type previously mentioned, there is (1) the possibility that the relation is not the same for field and cluster galaxies[24,25], and (2) the problem that the true intrinsic dispersion of the relation, if large, discriminates against intrinsically faint galaxies of a given linewidth and leads to an underestimate of the distances. It is therefore a matter of personal judgement how much weight one wants to attribute to the method. It is in any case, however, satisfactory to see that the 21 cm linewidth method, as it begins to mature, leads to results which are now consistent with the established distance scale.

This agreement is particularly satisfactory because it reinforces the time-scale agreement between the Hubble time of $H_0^{-1}\,(50) = 19.5 \times 10^3$ Myr the age of the chemical elements at $\sim 20 \times 10^3$ Myr (ref. 26), and the age of the globular clusters in our Galaxy at $\sim 18 \times 10^3$ Myr (refs 27, 28).

A helix stop signal in the isolated S-peptide of ribonuclease A

Peter S. Kim & Robert L. Baldwin

Department of Biochemistry, Stanford University Medical Center, Stanford, California 94305, USA

The isolated S-peptide (residues 1–20 of ribonuclease A) is known to show partial α-helix formation in aqueous solutions at low temperatures. We show here that the helix is limited to certain residues, including ones that are helical in the intact protein, and that a functional helix termination signal exists in the isolated peptide.

THE α-helix is the most abundant unit of secondary structure in proteins. Most α-helices are quite short: the average length of α-helices in proteins is about 11 residues[1]. In contrast, the average length of α-helices is much longer in synthetic polypeptides (about 100 residues at the transition midpoint)[2], and therefore, α-helix termination signals exist in proteins. The nature of these helix termination signals is of fundamental interest with respect both to the mechanism of protein folding and the prediction of folding from amino acid sequence. An important question concerning the mechanism of protein folding is whether the helix start and stop signals function at early stages in folding when the α-helices and β-sheets are first formed, or whether tertiary interactions are required to fix the ends of helices.

The X-ray structures of RNase A[3] and of RNase S[4] show that RNase contains three short helices. [RNase S is an enzymatically active derivative of RNase A cleaved at the peptide bond between residues 20 and 21; the proteolysis products can be separated and are referred to as the S-peptide (residues 1–20) and the S-protein (residues 21–124)[5].] The structure of interest here is the α-helix formed by residues 3–13 (counting residues containing at least one α-helical H-bond). The crystal structure shows that the amide proton of Asp 14 (the next H-bond donor at the C-terminal end of the 3–13 helix) is H-bonded to the

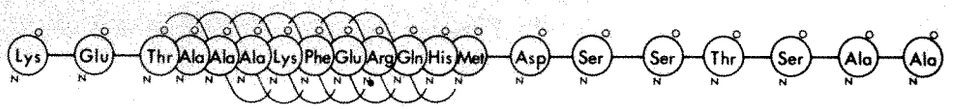

Fig. 1 Amino acid sequence of S-peptide (1–20), showing the α-helix formed by these residues in native RNase A[3] and RNase S[4]. S-peptide (1–20) was prepared and purified for us by V. MacCosham. RNase A (Sigma Type 1-AS, lot no. 81F-8015) was purified[18] and then digested with Subtilisin Carlberg (Sigma Type VIII, lot no. 48C-0164)[19]. S-peptide was purified by ion exchange chromatography (SP-Sephadex C25 in 0.01 M HCl; 0.05–1.0 M NaCl gradient) and by gel filtration (Sephadex G-25 fine in 0.01 M HCl). Two peptides were separated using the purification procedure above, and amino acid analysis (performed at the Department of Biochemistry and Biophysics, University of California, Davis) indicated that the peptides were S-peptide (1–19) and S-peptide (1–20) (see ref. 20). All experiments reported here were made using purified S-peptide (1–20).

carbonyl oxygen of Val 47 in a tertiary interaction (contrast Fig. 4 f of ref. 6). Thus, this tertiary interaction holds residue 14 in a non-helical conformation. One would like to know whether this tertiary interaction is required for the localization of the 3–13 helix, or if a functional helix termination signal exists in the absence of tertiary interactions (for example in an early protein folding intermediate).

One direct approach for investigating the nature of helix termination signals is to study the folding of protein fragments. Until recently, however, this has not been possible because even large fragments of single-domain proteins have been found to be unfolded in aqueous solutions[7,8]. Moreover, 'host-guest' data for α-helix formation in water by synthetic polypeptides[9] indicate that short α-helices (<20 residues) are always unstable in water, regardless of the amino acid composition. These data have led to the conclusion that secondary structure in protein fragments is not stable in the absence of stabilizing tertiary structure interactions.

Nevertheless, both the C-peptide of RNase A (residues 1–13, obtained by cyanogen bromide cleavage at Met-13, yielding HSer-13 lactone as the C-terminal residue), and the S-peptide (residues 1–20) show partial helix formation in aqueous solutions as judged by circular dichroism (CD) spectra and by ^{1}H nuclear magnetic resonance (NMR) studies[10–13]. Some characteristics of the helix formed by the C-peptide are as follows. (1) Up to ~30% helix content is observed in water near 0 °C[11], which is 1,000 times greater than the helix content predicted using data from host–guest studies. (2) Helix formation is strongly dependent on temperature, and C-peptide is essentially unfolded in aqueous solutions at 25 °C[10,11]. (3) Equilibrium sedimentation measurements show that C-peptide is monomeric at concentrations up to 2 mg ml^{-1} in conditions in which helix formation occurs (1 °C, 0.1 M ionic strength)[10]. (4) The *p*H dependence of helix stability follows a bell-shaped curve[11], with maximum helix formation occurring near *p*H 5. A possible explanation for this *p*H dependence has been given[11]: a salt bridge between the ionized sidechains of Glu 9$^-$ and His 12$^+$ could stabilize the helix.

Here we use S-peptide (1–20), which contains the first 20 amino acids of RNase A, to ask whether the α-helix formed by the isolated peptide stops near residue 13 (the last residue of this helix in native RNase A or RNase S). Five residues with low helical propensity occur in a stretch next to the 3–13 helix (residues 14–18, see Fig. 1). Although studies of helix formation in random copolymers allow some amino acid residues to be classified as 'helix formers' and others as 'helix breakers', the reported stability constant (s) values for helix growth span a very narrow range ($s = 0.5$–1.3 for all residues studied)[9]. The 'cooperative length' of an α-helix is about 100 residues[2] = $1/\sigma^{1/2}$, where σ is the helix nucleation constant; $\sigma \sim 10^{-4}$ for all residues studied[9]. Predicted distributions of helix length for short peptides (including end effects) containing a single residue type are discussed by Schellman[14]. For a 20 residue peptide, these results show that a significant fraction of the α-helices formed will include all 20 residues, in the absence of helix termination signals.

To determine whether the α-helix formed by S-peptide (1–20) is localized, we have followed the ^{1}H-NMR chemical shifts of various sidechain groups as the helix is unfolded. The helices formed by S-peptide (1–20) and C-peptide lactone can be unfolded by increasing temperature[11,13], GuHCl[12], or urea, as we report here. Since the stability of the S-peptide (1–20) helix is *p*H dependent[13], we have also monitored the ^{1}H-NMR chemical shifts of sidechain groups as the helix content is changed by varying *p*H. Of particular interest are those amino acid residue types that are present both within and outside the native 3–13 α-helix (Fig. 1). These include the alanine residues (Ala 4, 5, and 6 are in the helix of native RNase A, whereas Ala 19 and 20 are not), and the threonine residues (Thr 3 is in the native helix and Thr 17 is not). The β-CH_3 group of alanine is physically close to the α-helix backbone, and the alanine β-CH_3 resonance is expected to shift with helix formation, as has already been observed for Ala 4, 5, and 6 in the C-peptide lactone helix[12]. The γ-CH_3 resonance of Thr 3 also shifts as the C-peptide lactone helix is formed[11], and here we ask whether the Thr 17 (γ-CH_3) resonance shows a comparable helix shift.

Table 1 Comparison between NMR helix shifts and CD changes in S-peptide (1–20) and C-peptide lactone (1–13).

NMR resonance	Peptide	Helix shift $\Delta\delta$ (p.p.m.)*	Molar peptide CD change $\Delta[\theta]_{222}$ (deg cm^2 dmol^{-1})†	Normalized helix shift $\Delta\delta/\Delta[\theta]_{222}$	Ratio (R) of normalized helix shift S-Peptide (1–20): C-Peptide lactone‡
Thr 3 (γCH_3)	S-peptide (1–20)	0.071	4.30×10^4	1.65×10^{-6}	1.07
Thr 3 (γCH_3)	C-peptide (lactone)	0.103	6.69×10^4	1.54×10^{-6}	
Phe 8 (ϕH)§	S-peptide (1–20)	−0.051	4.30×10^4	-1.19×10^{-6}	1.04
Phe 8 (ϕH)	C-peptide (lactone)	−0.076	6.69×10^4	-1.14×10^{-6}	

* Difference in chemical shift between 4 °C and 47 °C, at the optimum *p*H for helix formation. S-peptide (1–20) data are for *p*H 3.8. Data for C-peptide lactone (*p*H 5.0) are from ref. 11. Temperature dependence of chemical shift, in absence of helix formation, not taken into account.

† Difference in $[\theta]_{222}$ per mole peptide between 3 °C and 40 °C (*p*H 3.8) for S-peptide (1–20)[13] and between 3 °C and 45 °C (*p*H 5.0) for C-peptide lactone[11].

‡ Predicted value for R is 1.0 if the helix is localized to the same residues in both peptides and if the helix shifts are the same for both peptides at 100% helix formation. If the helices propagate to the ends of both peptides, then R is predicted to be ≤ 0.63 ($\frac{12}{19}$, corresponding to the ratio of the number of peptide carbonyl groups). Due to end effects on the apparent molar ellipticity of an α-helix (see ref. 24 and refs therein), R will be <0.63 if the helices include all residues of both peptides.

§ There are six visible resonance lines for Phe 8, and only three of them shift significantly with helix formation[11]. Values are reported for the middle resonance of these three.

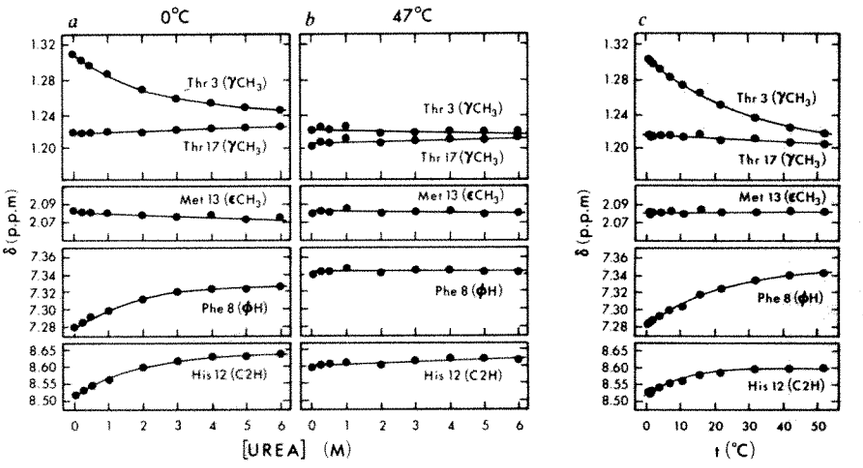

Fig. 2 *a*, Urea dependence of ^{1}H-NMR chemical shift for some side-chain resonances in S-peptide (1–20): 0 °C, *p*H 3.8, 0.1 M NaCl, D_2O. *b*, Urea dependence: 47 °C, *p*H 3.8, 0.1 M NaCl, D_2O. *c*, Temperature dependence of ^{1}H-NMR chemical shift for some side-chain resonances in S-peptide (1–20): *p*H 3.8, 0.1 M NaCl, D_2O. The average chemical shift for the threonine γ-CH_3 doublets are shown. There are six visible resonance lines for Phe 8 (ϕH), and only three of them shift significantly with helix formation. The middle resonance of these three is shown.

Methods: All samples contained 0.1 M NaCl in D_2O. *p*H was adjusted with DCl or NaOD, and *p*H values refer to meter readings without isotope corrections. Urea and GuHCl were Schwarz-Mann ultrapure grade. Urea-d_4 and GuDCl-d_6 were prepared by repeated lyophilization from D_2O (Liquid Carbonic, 99.7% C). All other chemicals were reagent grade. Fourier-transform proton NMR spectra were recorded on a modified Bruker 360 MHz instrument at the Stanford Magnetic Resonance Facility. All chemical shifts are reported relative to the internal standard, TSP. Corrections were made for the *p*H dependence of the TSP signal[21]. Resolution-enhanced NMR spectra were obtained by multiplication of the free-induction decay with either a double exponential[22] or a sine bell function[23]. Damping of the free-induction decay in the presence of urea was observed (contrast ref. 20), but did not affect the spectra of the peptide. Resonance assignments have been or will be given elsewhere[20] (A. Bierzynski *et al.* manuscript in preparation). The Thr 17 (γ-CH_3) resonance was assigned by comparing the spectra of S-peptide (1–15) and S-peptide (1–20) in the unfolded state (5.0 M GuDCl, 0° or 47 °C).

Side-chain resonances

The optimum conditions for α-helix formation in aqueous solutions of S-peptide (1–20), as judged by CD, are *p*H 3.8, 0 °C[13]. As urea is added in these conditions, some side-chain resonances show chemical shift changes while others do not (Fig. 2*a*). The side-chain resonances of Thr 3, Phe 8 and His 12 show changes in chemical shift as the helix is unfolded with urea. However, when the α-helix is already thermally unfolded at 47 °C, urea does not affect the chemical shifts of these resonances (Fig. 2*b*).

In contrast to Thr 3, the side-chain resonance of Thr 17 does not change as the helix is unfolded (Fig. 2). Thus, Thr 17 is probably not in the α-helix formed by the isolated S-peptide (1–20). End effects (helix fraying) are not sufficient to explain the difference observed between Thr 3 and Thr 17, because Thr 3 is the third residue from the amino-terminus and Thr 17 is the fourth residue from the carboxyl-terminus.

The S-CH_3 resonance of Met 13 does not shift as urea is added (Fig. 2). However, the lack of a helix shift for Met 13 is difficult to interpret for two related reasons. (1) The S-CH_3 sidechain group of methionine is four bonds removed from the peptide backbone, and it may be possible for the helix to form without perturbing the magnetic environment of the S-CH_3 protons. (2) We do not have a positive control demonstrating a helix shift for a methionine S-CH_3 resonance, whereas with other resonances (for example threonine γ-CH_3), a positive control exists. It is therefore not possible to tell whether Met 13 is contained in the helix formed by isolated S-peptide (1–20). In native RNase A, Met 13 is the last residue in the α-helix. His 12 (ring C2H resonance) does show a helix shift (Fig. 2). The β-CH_3 resonances of Ala 4, 5, 6, 19, and 20 are not well separated in spectra taken in urea at high temperatures, or at high urea concentrations, 0 °C, and are therefore not depicted in Fig. 2.

The α-helices formed by both C-peptide lactone and S-peptide (1–20) unfold with increasing temperature[11,13]. Figure 2*c* depicts the temperature dependences of the chemical shifts for the resonances shown previously, at *p*H 3.8. The residues that show a helix shift for urea-induced unfolding (Fig. 2*a*) also show a temperature-induced helix shift (Fig. 2*c*). In particular, the Thr 17 resonance, which does not show a urea-induced helix shift (Fig. 2*a*), also does not show a temperature-induced shift (Fig. 2*c*), supporting the suggestion that the S-peptide (1–20) helix is localized.

Guanidine deuterochloride (GuDCl) is known to affect the chemical shifts of many side-chain resonances, and these changes are often not attributable to the unfolding of structure. Moreover, the effects of GuDCl on chemical shifts are dependent on neighbouring groups, suggesting that the effects are related to the binding of GuDCl to the peptide[12]. Our GuDCl titrations of S-peptide (1–20) at 37 °C, where the helix is thermally unfolded, also show GuDCl-induced changes in chemical shift (Fig. 3*b* and 4*b*) and some of these resonances continue to change between 3–5 M GuDCl, where S-peptide (1–20) should be in a 'random coil' conformation.

In addition, GuDCl appears to cause a 'salt effect' on the chemical shifts between 0 and 1 M GuDCl that does not appear to be related to helix structure for the following reasons. (1) The effect is observed even at 37 °C, where the helix is thermally unfolded (Fig. 3*b* and Fig. 4*b*). (2) Essentially all resonances show the salt-effect. These GuDCl-induced chemical shifts may be caused in part by effects of GuDCl on the internal standard (TSP). Both GuDCl and TSP are charged, and we have observed NaCl-dependent shifts of the TSP resonance relative to acetone or dioxane.

When the GuDCl titrations are performed at 0 °C (favouring helix formation), some resonances show changes in chemical shift that evidently are caused by helix unfolding (Fig. 3*a* and Fig. 4*a*). To determine the changes in chemical shift caused by helix unfolding, we have subtracted the GuDCl dependence of the chemical shifts at 37 °C, in the absence of helix formation, from the dependence at 0 °C where the helix is populated. The temperature difference curves for the GuDCl titrations are depicted in Fig. 3*c*. As was found with urea and temperature, the side-chain resonances of Thr 3, Phe 8, and His 12 show helix shifts with GuDCl, whereas those of Met 13 and Thr 17 do not (Fig. 3*c*).

An advantage of using GuDCl is that resonances are spread out which arise in similar regions of the NMR spectrum. In particular, the five alanine β-CH_3 groups (Ala 4, 5, 6, 19, and 20) give rise to ten resonance lines in the NMR spectrum of S-peptide (1–20). There is considerable overlap of these resonances in the spectrum, under conditions in which the helix is unfolded by urea or temperature. The interaction of GuDCl with the peptide results in the separation of these resonances in the spectrum (Fig. 4). The resonances listed as Ala I, II, III correspond to Ala 4, 5, 6 respectively (see Fig. 4 legend).

In S-peptide (1–20), as in C-peptide lactone[12], Ala 4, 5, and 6 show significant helix shifts; the difference between the GuDCl titration curves at 0° and at 37 °C is shown for each resonance in Fig. 4*c*. In marked contrast, Ala 19 and 20 do not show measurable helix shifts (Fig. 4*c*), supporting further the sugges-

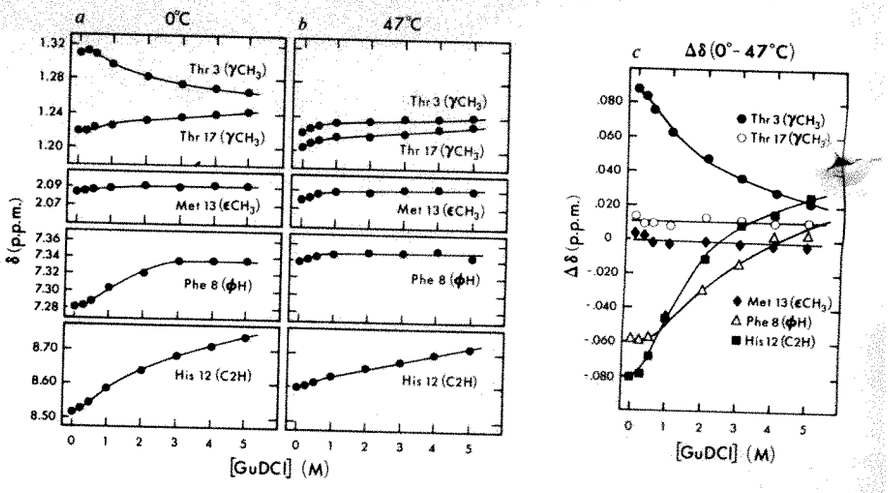

Fig. 3 GuDCl titrations of S-peptide (1–20). *a*, 0 °C, *p*H 3.8, 0.1 M NaCl, D_2O. *b*, 47 °C, *p*H 3.8, 0.1 M NaCl, D_2O. *c*, $\Delta\delta$ (0–47 °C); the difference in chemical shift between 0 °C and 47 °C.

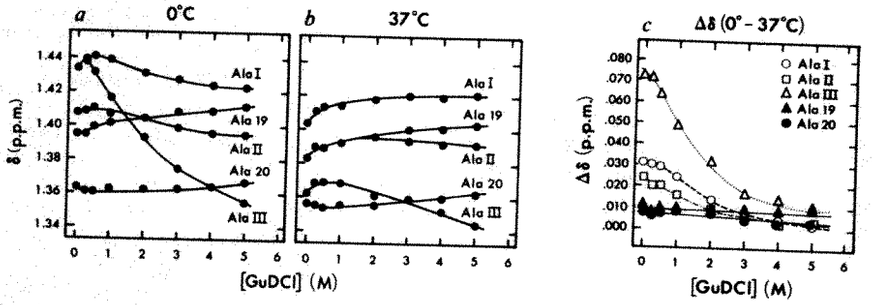

Fig. 4 GuDCl titrations of the alanine β-CH_3 resonances in S-peptide (1–20). *a*, 0 °C, *p*H 3.8, 0.1 M NaCl, D_2O. *b*, 37 °C, *p*H 3.8, 0.1 M NaCl, D_2O. *c*, $\Delta\delta$ (0–37 °C); the difference in chemical shift between 0 °C and 37 °C. The average chemical shift for each alanine β-CH_3 doublet is shown. The resonances numbered Ala I, II, III correspond to Ala 4, 5 and 6 respectively. These assignments were made, after submission of this paper, using a synthesized peptide containing deuterated alanine. The resonance assignments of Ala 19 and 20 were made by comparing the spectra of S-peptide (1–15) and S-peptide (1–20) in the unfolded state (5.0 M GuDCl, 0° or 37 °C) to locate Ala 19 and 20, and by *p*H titration of the α-COOH group of Ala 20, to locate Ala 20.

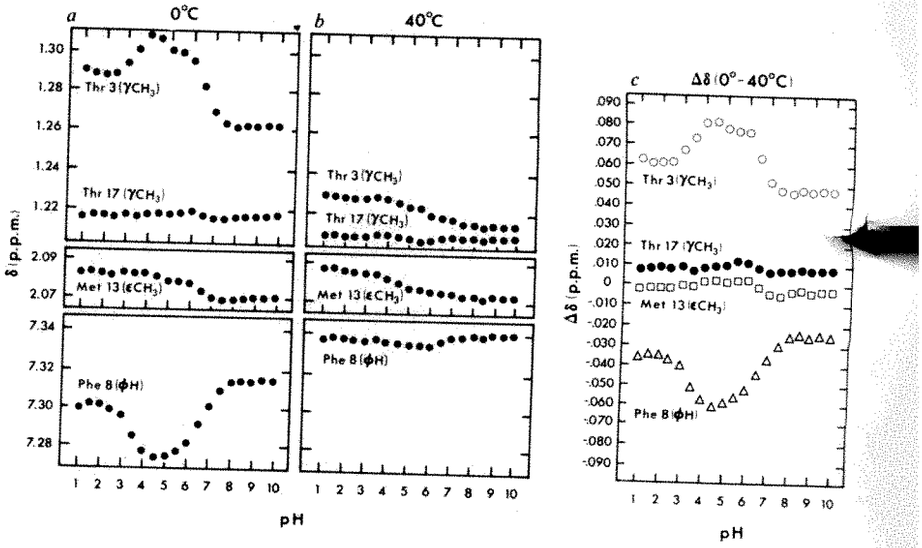

Fig. 5 *p*H titration of S-peptide (1–20). *a*, 0 °C, 0.1 M NaCl, D_2O. *b*, 40 °C, 0.1 M NaCl, D_2O. *c*, $\Delta\delta$ (0–40 °C); the difference in chemical shift between 0 °C and 40 °C. The *p*H titration of His 12 (C2H) is dominated by changes in chemical shift due to the titration of the imidizole ring and is not depicted. The Ala β-CH_3 resonances are not well separated in some conditions and are not shown.

tion that the α-helix formed by isolated S-peptide (1–20) is localized. The alanine β-CH_3 resonances are particularly useful indicators of helix formation. Only one bond separates the alanine β-CH_3 group from the peptide backbone. Moreover, rotation about this bond ($C_\alpha - C_\beta$) is fast on the NMR time scale under all conditions investigated here. A small linear shift is observed for Ala 20 as GuDCl is added, but this shift is clearly distinct from the helix shifts observed for Ala 4, 5, and 6 (Fig. 4*c*). The linear GuDCl shift for Ala 20 is probably related to the fact that Ala 20 is the last residue in the peptide, and contains the α-COO^- group.

Comparison with CD results

A direct comparison between the molar ellipticity change (222 nm) caused by helix formation for C-peptide lactone and for S-peptide (1–20) is not yet possible, for the following reasons. (1) Only partial helix formation has been observed for either peptide, even in the optimal helix-forming conditions. For C-peptide lactone, a helix content of 30% at *p*H 5.0, 0 °C, has been estimated from CD measurements. It is likely that, in these conditions, 30% of the molecules are helical and 70% are in a random coil conformation; almost all resonances of C-peptide lactone show shifts as the helix is formed[11] (A.

Bierzynski *et al.*, manuscript in preparation). Any comparison between the CD changes on helix formation for the two peptides depends critically on the relative stabilities of the helices formed by the two peptides. (2) The *p*H–stability profiles for C-peptide lactone[11] and for S-peptide[13] differ in important respects: the optimal *p*H is 5.0 for C-peptide lactone but 3.8 for S-peptide. Consequently, a comparison between helix stabilities at any given *p*H is arbitrary. A comparison between the molar ellipticity changes on helix formation by the two peptides has been made earlier, at *p*H 5.5, by Brown and Klee[15], who were not aware either of the strong *p*H dependence of helix stability or of the different *p*H–stability profiles of the two helices. Also, they studied helix formation in an unresolved mixture of C-peptide lactone and C-peptide carboxylate, without knowing the striking difference between the helix-forming properties of these two peptides (contrast ref. 13).

We have made an approximate comparison between the molar ellipticity changes on helix formation for C-peptide lactone and S-peptide (1–20) in the following way. We assume that the residues within the helix have the same structure in the helical conformation of both peptides and consequently that the helix shifts for 100% helix formation are the same for both helices, measured for any of several side-chain resonances. From the observed helix shifts, we calculate a ratio for the extent of helix formation for the two peptides. This ratio is then compared to the ratio of ellipticity changes (per mole peptide). The results (Table 1) show that these two ratios are the same, indicating that approximately the same number of residues participate in helix formation in both peptides. This is consistent with the conclusion that the helix in S-peptide (1–20) terminates before Thr 17 and possibly near Met 13.

*p*H dependence of helix stability

As mentioned above, the stabilities of both the S-peptide (1–20) helix and the C-peptide lactone helix are strongly dependent on *p*H. However, the *p*H dependence of $[\theta]_{222}$ is more complex in S-peptide (1–20)[13] than in C-peptide lactone[11]. At low temperatures, where the helix is populated, the *p*H dependence of $[\theta]_{222}$ shows a complex curve[13], in contrast with the almost symmetric bell-shaped curve found with C-peptide lactone[11]. When either peptide is thermally unfolded (40–45 °C), $[\theta]_{222}$ is essentially independent of *p*H[11,13]. These results suggest that charged residue(s) which affect helix stability exist in S-peptide (1–20) that are not present in C-peptide lactone.

We have monitored the *p*H dependence of chemical shift for some resonances of S-peptide (1–20) at 0 °C and 40 °C, and the results are depicted in Fig. 5. At 40 °C, some resonances show *p*H-dependent chemical shifts (Fig. 5*b*) that are unrelated to helix formation. We again take the difference in chemical shift between 0 °C and 40 °C, to obtain the shifts that are due to helix formation. The results (Fig. 5*c*) show that both Thr 3 and Phe 8 give *p*H-dependent helix shifts that are qualitatively similar to the *p*H dependence of $[\theta]_{222}$ for S-peptide (1–20)[13]. In contrast, Thur 17 and Met 13 ($S\text{-}CH_3$) do not show a significant *p*H-dependent shift in the temperature difference plot (Fig. 5*c*). These data agree with the conclusion that S-peptide (1–20) contains a functional helix termination signal, and they suggest that the same residues are contained within the helix at all *p*H values where helix formation is observed.

NMR and helix termination

In the present study, we have monitored side-chain resonances and have measured 'helix shifts' (changes in chemical shift caused by alterations in the helix stability with temperature, urea, GuDCl, or *p*H) to determine whether a given residue participates in helix formation. The fact that self-consistent results are obtained with all four methods of changing the helix content lends support to this procedure. Nevertheless, the results with the $S\text{-}CH_3$ resonance of Met 13 point out a possible danger in using this approach: the group may be too far removed from the peptide backbone to show a significant change in chemical shift on helix formation. In this regard, the results with the $\beta\text{-}CH_3$ resonances of Ala 4, 5, 6, 19, and 20 are particularly valuable in indicating helix termination within the peptide, because the $\beta\text{-}CH_3$ group of Ala is very close to the peptide backbone of the helix. In order to study these five Ala resonances, it was necessary to make use of the ability of GuDCl to spread out the chemical shifts of groups of the same residue type.

Helix termination signal

Measurements of the equilibrium constant for nucleation (σ) in homopolymers and random copolymers[9] indicate that σ is always very small ($\sigma \sim 10^{-4}$). The cooperative length of an α-helix in aqueous solutions is thus predicted to be about 100 residues[2] ($=1/\sigma^{1/2}$). In contrast, our results indicate that the helix formed by S-peptide (1–20) is localized to certain residues. The features of the naturally occurring amino acid sequence of S-peptide (1–20) that are responsible for helix termination are of obvious interest.

In order to understand the mechanism of helix termination in S-peptide (1–20), we will need to have a more detailed description of termination. One wants to know at which residue the helix terminates and whether termination is gradual (spread out over a few residues) or abrupt. In future work it will be useful to use ^{13}C-enriched amino acids to monitor backbone resonances, and to monitor additional side-chain resonances with two-dimensional NMR techniques. One would also like to find conditions (perhaps with new derivatives of the S-peptide and C-peptide) in which helix formation goes to completion for those residues in the helix. Then the molar CD changes for helix formation in different peptides can be compared directly, and the NMR results can be extended by measuring amide proton exchange rates and nuclear Overhauser effects.

We consider here two contrasting models for helix termination in peptides that may also play a role in protein folding. Our present data are largely consistent with a simple helix termination mechanism in which the amino acid sequence increases the helix nucleation constant (σ), and therefore decreases the cooperative length of the helix (for example, increasing σ to 10^{-2} would decrease the cooperative length to 10 residues). Then, a stretch of residues with low helix propensity (for example, residues 14–18 of S-peptide) would prevent propagation of the helix. The observed stabilities of the C-peptide lactone and S-peptide (1–20) helices are 1,000-fold greater than that predicted using the value of $\sigma \sim 10^{-4}$ obtained from polymer studies. If σ were larger in S-peptide, for example due to specific interactions between sidechains, then the increased stability and termination of the S-peptide (1–20) helix could be explained. On the other hand, the mechanism of helix termination may directly involve specific interactions between sidechain groups. For example, model building shows that a H-bonding interaction between the sidechains of His 12^+ and Asp 14^- would prevent propagation of the S-peptide (1–20) helix past residue 13. The *p*H dependence of S-peptide (1–20) is more complex than that of C-peptide lactone[13], and the additional ionizing groups in S-peptide (1–20) involve only Asp 14 and the $\alpha\text{-}COO^-$ group of Ala 20. More work is needed to distinguish between these and other possible explanations of helix termination in S-peptide.

Mechanism of protein folding

Studies of C-peptide lactone[11] and S-peptide[13] have demonstrated that isolated units of secondary structure can have significant stability in water. The data presented here suggest that functional termination signals can exist in isolated units of secondary structure. These results are consistent with the simple framework model for protein folding in which the amino acid sequence directly determines the positions of the α-helices and β-sheets, and these secondary structures then pair to form the tertiary fold. Since C-peptide lactone and S-peptide provide the first examples of α-helix formation and termination in aqueous solutions of a short peptide fragment of a protein, it is important to point out that they provide only isolated examples, and many

more examples will be needed to base conclusions about the folding mechanism.

These data are encouraging with regard to predicting secondary structure from amino acid sequence because they suggest that helix formation in the isolated S-peptide is localized to the same, or nearly the same, residues as in native RNase A. It is interesting that present schemes for predicting secondary structure are more successful in finding the locations of helices than in defining their endpoints[17]. Experiments of the type described here, with peptides of specified amino acid sequence, may provide clues about the nature of helix termination signals.

We thank Drs K. Kuwajima and D. E. Wemmer for discussions, S. G. Boxer for use of his computing facilities and V. MacCosham for technical assistance. This work was supported by NIH grant 2 RO1 GM 19988-22. P.S.K. is a predoctoral fellow of the Medical Scientist Training Program. Use of the Stanford Magnetic Resonance Facility (supported by NSF grant GP 23633 and NIH grant RR 00711) is acknowledged.

Note added in proof: A recent ^{1}H-NMR study[25] (published after submission of this article) of helix formation by S-peptide (1–19) agrees with our conclusion that the helix is limited to certain residues including the helical residues of RNase A.

Activation of a translocated human c-*myc* gene by an enhancer in the immunoglobulin heavy-chain locus

Adrian C. Hayday*, Stephen D. Gillies*, Haruo Saito*, Charles Wood*, Klas Wiman†, William S. Hayward† & Susumu Tonegawa*

* Center for Cancer Research and Department of Biology, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

*A tissue-specific transcriptional enhancer element that is associated with the human immunoglobulin heavy-chain locus is defined. In a non-Hodgkin's lymphoma that contains a translocated c-*myc *gene this enhancer is retained on the 14q$^+$ chromosome and occurs within sequences shown to activate previously cryptic promoters of the c-*myc *gene.*

A FUNCTIONAL immunoglobulin gene is generated somatically during the differentiation of B lymphocytes by a set of developmentally regulated gene rearrangements[1]. The major function of these rearrangements is to generate a diverse set of complete immunoglobulin genes from a limited number of inherited gene segments.

Another important role of these rearrangements has recently been identified at least for the mouse immunoglobulin heavy-chain genes[2–4]. In an individual B lymphocyte and its progenies, only one of a few hundred copies of the variable (V) gene segments is expressed. This activation of a specific V gene segment results from its direct rearrangement into the vicinity of a transcriptional enhancer element that is located upstream of the constant (C) region gene segments, between the joining (J) segments and the switch (S) region. Interestingly, the immunoglobulin gene-associated enhancer functions in a tissue-specific manner, suggesting a more general involvement of cellular enhancer elements in tissue-specific expression of eukaryotic genes during cell differentiation.

Another biological process in which gene rearrangements and enhancer elements may play a critical, albeit adventitious, role is tumorigenesis. A model supporting this notion comes from the studies on the chicken leukaemogenesis induced by the non-acute avian leukosis virus (ALV). By integrating close to the cellular oncogene, c-*myc*, the ALV provirus via its transcriptional promoter or enhancer element can lead to increased levels of c-*myc* transcription[5,6]. It has recently been shown that the c-*myc* gene is translocated into an immunoglobulin locus in certain lymphoid neoplasms of both mice and men[7–12]. Thus, murine c-*myc* gene is recombined into the immunoglobulin heavy-chain locus in BALB/c plasmacytomas characterized by t(12:15) translocations[7,9–11]. Likewise, in a majority of the many Burkitt's lymphomas or non-Hodgkin's lymphomas characterized by t(8:14) (q24; q32) translocations, the c-*myc* gene is recombined into the immunoglobulin heavy-chain locus[8,11,12]. It has generally been considered that in these and other neoplasms where nonrandom chromosomal translocations have been observed, c-*onc* genes are activated by the translocations[13–15].

To understand the relationship between the translocation and activation of a c-*myc* gene we have been analysing the structure and expression of normal and translocated human c-*myc* genes. The results presented here demonstrate that the human immunoglobulin heavy-chain locus carries a transcriptional enhancer element analogous to its mouse counterpart, and that this enhancer element may be playing a direct part in the activation of the translocated c-*myc* gene in some lymphoid neoplasms.

c-*myc* translocation in Manca cells

The non-Hodgkin's lymphoma, Manca[16], shows a chromosome translocation (t(8:14)(q24; q32)) that is characteristic of many

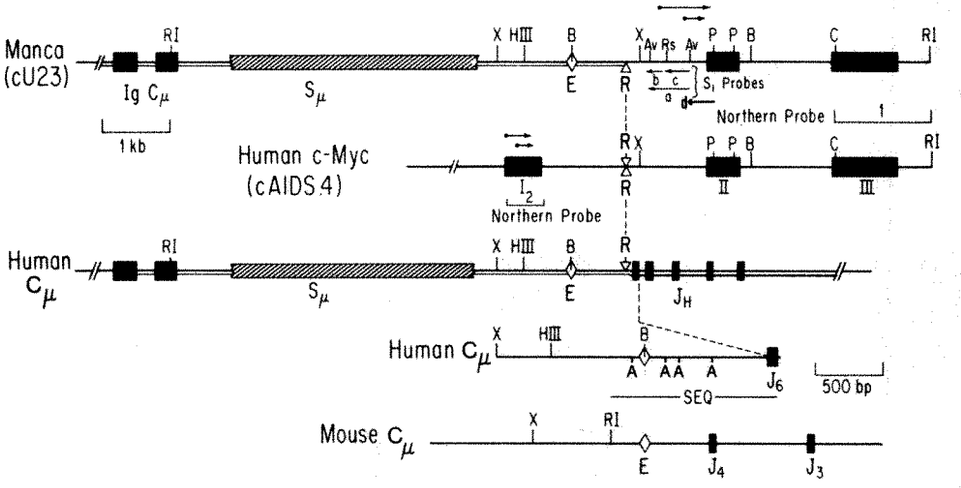

Fig. 1 A comparison of the human c-*myc* gene and the C_μ region of the human immunoglobulin heavy-chain locus to the C_μ–c-*myc* joining region of the 14:8 translocated chromosome from Manca cells. Exons are shown as solid boxes; chromosome 14 sequences as a double line; and chromosome 8 sequences as a single line. R indicates the site of recombination between the two chromosomes. E is a transcriptional enhancer element, which was previously identified for the mouse immunoglobulin heavy-chain locus[2–4] and the identification of the human equivalent is reported here. S_μ, C_μ switch sequences; J_μ, joining segments. The J_μ segments are defined on the basis of data presented in ref. 40, and our own sequencing[41]. The horizontal arrows indicate the initiation sites and directions of transcription. Restriction sites: RI, *Eco*RI; X, *Xba*I; H, *Hin*dIII; Av, *Ava*I; Rs, *Rsa*I; P, *Pst*I; B, *Bgl*II; C, *Cla*I; A, *Alu*I (the complete map is only shown for the first three of these). 1 and 2 delineate the extent of the probes used in the Northern blot experiments. The cloning of the recombination region of the translocated chromosome into cosmid pTCF[19] will be described elsewhere (K.W. *et al.*, manuscript in preparation). The unrearranged c-*myc* gene was also cloned into a cosmid. Colonies were screened with the Northern probe 1. The definition of the c-*myc* gene will be described[22].

Burkitt's lymphomas[14,15]. *In situ* hybridization of a v-*myc* probe[17] to Manca chromosomes indicates that the human c-*myc* locus is on that portion of chromosome 8 [12,18] that is translocated (data not shown).

From a cosmid library[19] of Manca DNA a clone, cU23 was isolated that hybridized both to v-*myc* and to pH18-C1-10, a plasmid containing the immunoglobulin heavy-chain C_μ gene and sequences immediately 5′ to it[20]. Southern blot analysis[21] of Manca DNA indicated that the linkage of c-*myc* and immunoglobulin heavy-chain gene sequences detected in cU23 had occurred in the human cells, and not upon cloning (data not shown). A detailed map of clone cU23 in the region of c-*myc*–C_μ linkage was derived by restriction analysis and DNA sequencing (K. W. *et al.*, manuscript in preparation), and was compared with maps of human germ-line C_μ and c-*myc* genes, contained on plasmid pH18-Cl-10 and cosmid cAIDS4 respectively (Fig. 1). The latter clone was described previously[22]. It can be deduced that in Manca DNA, the human c-*myc* gene is fused head-to-head with the C_μ gene, about 6.5 kilobases (kb) 5′ to the first C_μ exon. The junction on chromosome 14 lies between S_μ and J_H6, at a point that is not normally used for the productive rearrangement of an immunoglobulin heavy-chain gene. The junction on chromosome 8 occurs between exons I and II of the c-*myc* gene. As a result, the Manca DNA cloned in cU23 contains neither exon I nor the normal transcriptional start sites[22] of the human c-*myc* gene. Instead, c-*myc* exons II and III are fused to C_μ sequences that include a stretch of DNA between S_μ and J_H that is in an analogous location to sequences in the mouse genome shown to have tissue-specific transcriptional enhancing activity[2–4] (region 'E' in Fig. 1). The translation of transcripts of the human c-*myc* gene begins within exon II, at an initiation AUG codon that is retained, and presumably used, in transcripts of the translocated c-*myc* gene in Manca cells.

Multiple transcription initiation sites

Northern blot analysis of RNA from Manca cells indicates a high level of c-*myc* transcription (Fig. 2*A*). It is clear that there are multiple transcripts hybridizing to the c-*myc* Northern probe 1 (see Fig. 1). The level of c-*myc* transcription in Manca cells is the highest that we have detected in any cell line (which include other Burkitt's lymphomas, and Epstein–Barr virus-immortalized lymphoblastoid cells) except the promyelocytic leukaemia cell line HL60 (data not shown). The relevance of this comparison is unclear, however, as all these cells are growth transformed. An alternative approach is to compare the level of transcription of the rearranged c-*myc* gene in Manca cells with that of the unrearranged allele; with a probe specific for exon I no transcription of the unrearranged c-*myc* gene can be detected in Manca cells (K.W. *et al.*, manuscript in preparation). Therefore, the high c-*myc* level of transcription in Manca cells all derives from the translocated allele.

The initiation points of c-*myc* transcripts in Manca cells were mapped by S_1 nuclease protection experiments[23,24] using the probes shown at the bottom of Fig. 2. The major initiation site (site 1; see Fig. 2) for c-*myc* transcripts occurs about 636 base pairs (bp) upstream of c-*myc* exon II, within what would ordinarily be intron I of the c-*myc* gene. The nucleotide numbering system used to denote the initiation points is that of Colby *et al.*[25], whose sequence begins within intron I of the human c-*myc* gene such that nucleotide 1,000 defines the start of exon II. Transcripts initiating at site I (nucleotide 364) form S_1-resistant hybrids with probes b and a of 66 base pairs (bp) and 359 bp respectively (Fig. 2*B*, *C*). Downstream of site I, at nucleotide 378, is a weaker initiation point, Ia (Fig. 2*B*, *C*). As has been previously noted[25], upstream of initiation sites I and Ia are sequences related to the consensus TATA box[26,27] commonly found 5′ of genes transcribed by RNA polymerase II (see Fig. 3). Initiating at around nucleotide 873 are further transcripts, which form S_1 nuclease-resistant hybrids of length 192 bp with probe d (data not shown), and 28 bp upstream of this site occurs the sequence TTTATT (Fig. 3). In addition to these initiation sites, an S_1 sensitive site (X) in hybrids between Manca RNA and either probe a or c is detected at around nucleotide 520. However, the assignment of an initiation site to this position is uncertain, an S_1-sensitive site also being apparent at this position in hybrids between probes a or c and yeast RNA on long exposures.

If transcripts initiating at these sites were to have no functional splice sites 5′ of the junction between exon II and the following intron, then the processed RNAs would range in size from 1,660 to 2,450 nucleotides (not including the poly(A) tail[28]). That this is the case is suggested by cDNA cloning, which has revealed a contiguous transcript extending upstream from exon II at least as far as position 660. Beyond this point the S_1 nuclease-sensitive sites have been confirmed as initiation (as opposed to splice) sites by primer extension analyses. For example, reverse transcripts of Manca cell RNA using the primer shown in Fig. 2*B* extend as far as nucleotide 364. Further primer extensions (for example using S_1 probe b) indicate no initiation sites upstream of those characterized here (data not shown).

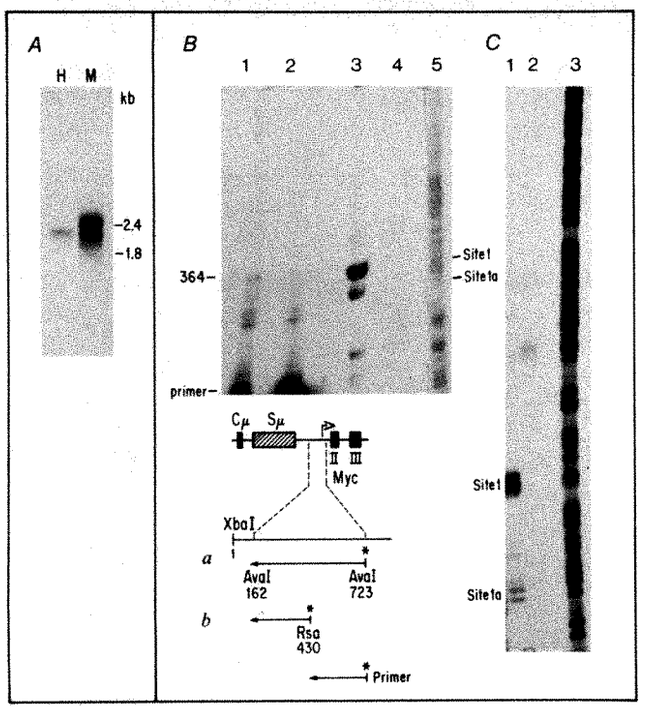

Fig. 2 ***A***, Northern blot analysis[42] using the probe 1 shown in Fig. 1 of mRNA from: lane H, HeLa cells (1 μg); lane M, Manca cells (0.3 μg). ***B***, Lanes 1 and 2 show a primer extension analysis[43], and lanes 3 and 4 an S_1 nuclease mapping analysis[23,24] of: lanes 1 and 3, Manca cell mRNA; lanes 2 and 4, yeast mRNA. The probes used are 'a' and 'primer' shown in the diagram below the photograph of the blot, and were strand separated and end labelled[41] before hybridization. The nucleotide numbering system derives from ref. 25, and starts (nucleotide 1) at the *Xba*I site in intron I of the human c-*myc* gene. Sites 1 and 1a are referred to in the text; site 1 centres on nucleotide 364, and the mark indicating this position on the right of the figure shows the correspondence between the primer extension and S_1 signals in lanes 1 and 3. Lane 5 is a pyrimidine analysis[41] of the sense strand of the probes, from which the nucleotide positions of the DNA–RNA discontinuity could be determined (see Fig. 3). ***C***, S_1 nuclease analysis using the probe 'b' shown in the diagram below *B* of mRNA from: lane 1, Manca cells; lane 2, yeast cells. Lane 3 is the same type of reaction as shown in lane 5 of *B*, but using probe b.
Methods: The S_1 nuclease reactions contained either 100 ng Manca cell mRNA plus 20 μg yeast RNA, or only the yeast RNA. For the S_1 analysis 5×10^4 c.p.m. of probe was used per reaction, and for the primer extension analysis 2×10^4 c.p.m. of probe was used per reaction. The probes were annealed to the RNA at 53 °C for 4 h (except in the case of probe b, which was annealed at 30 °C for 12–16 h). S_1 reactions were performed at 15 °C for 3 h, and primer extension reactions at 41 °C for 45 min. A 6% acrylamide gel was used for *B*, and run for 7 h, and an 8% gel run for 3 h for *C*.

Transcriptional enhancer element

We have previously shown that sequences derived from the J_H–C_μ region of the mouse immunoglobulin heavy-chain locus contain a DNA element that enhances the transcription of the associated gene in a manner largely independent of both position and orientation[2]. The translocation of the c-*myc* gene in Manca cell DNA just 300 bp downstream of the human J_H cluster (Fig. 1) suggested that the high level of c-*myc* transcription in Manca cells (Fig. 2*A*) might be due to a human enhancer element located in an analogous region to that in the mouse ('E' in Fig. 1).

To test this hypothesis, we first attempted to identify the putative human enhancer element. For this purpose, the 2.2 kilobase (kb) *Xba*I fragment (see Fig. 1) containing most of the sequence between the J_H cluster and S_μ, plus about 330 bp derived from the 5′ flanking region of the translocated, truncated c-*myc* gene, was inserted into the *Eco*RI site of plasmid pSER[2]. This plasmid was derived from pSV2.gpt[29] (which contains the mycophenolic acid-resistance conferring gene *Ecogpt*) by deletion from the latter of the SV40 enhancer sequences. As a result, pSER transforms cells to mycophenolic acid resistance (gpt^+ phenotype) at a much lower frequency than does pSV2.gpt (see Table 1). The original level of transformation can be restored by the insertion into the *Eco*RI site of pSER of the mouse immunoglobulin heavy-chain locus enhancer element[2]. As shown in Table 1, the insertion in either orientation of the human *Xba*I fragment into the *Eco*RI site of pSER (2.3 kb upstream of the *Ecogpt* gene) restored the gpt^+ transformation efficiency to a level even exceeding (by about eightfold) that of pSV2 gpt. The transformation efficiency of pSV2 gpt was itself increased 5–10-fold by insertion of the *Xba*I into its *Eco*RI site. Other fragments of mouse and human immunoglobulin heavy-chain loci DNA had no significant effects on transformation frequencies when inserted into pSER of pSV2.gpt. Also, like its murine counterpart the effect of the *Xba*I fragment was tissue-specific: with rodent fibroblasts the transformation efficiencies of pSERXa and pSERXb were over 100 times lower that of pSV2gpt. In a further experiment the 2.2 kb *Xba*I fragment was dissected by cleavage with *Alu*I, and some of the resulting fragments also tested in the pSER assay. Most, if not all the enhancing activity could be attributed to the 279 bp fragment, *Alu*.a (delineated by the two *Alu*I sites flanking the *Bgl*I site shown in the expanded map of the human C_μ gene in Fig. 1).

These transformation experiments strongly suggest that the 2.2 kb human *Xba*I fragment contains a tissue-specific transcriptional enhancer element. To demonstrate this point more directly we examined the effect of this DNA fragment on the transcription of a mouse immunoglobulin γ2b gene. The plasmid pSV.γ2bΔ$X_{2/4}$ contains a functionally rearranged mouse γ2b gene from which most of the sequences (including the enhancer element) between *V–D–J* and *C* exons have been deleted[2]. The plasmid also contains the selectable *Ecogpt* gene. J558L cells transformed to mycophenolic acid resistance by pSV.γ2bΔ$X_{2/4}$ express almost no γ2b heavy-chain RNA[2]. A high level of γ2b expression can be restored by re-insertion (either upstream or downstream of the *V–D–J* promoter) into plasmid pSV·γ2bΔ$X_{2/4}$ of the mouse enhancer[2], and similarly by insertion of the human *Xba*I fragment (Fig. 4). In this experiment, pools of cells transformed to a gpt^+ phenotype by pSV·γ2bΔ$X_{2/4}$ and its derivatives were assayed for γ2b gene expression by S_1 nuclease protection. The mouse enhancer was equally effective whether inserted upstream or downstream of the γ2b *V–D–J* promoter. By contrast the level of the γ2b gene transcription attained by the human enhancer was somewhat variable depending on its position, the highest level of expression being obtained when the enhancer was inserted upstream of the promoter in the opposite orientation to the direction of transcription (Fig. 4). Interestingly, the relative orientations of enhancer and promoter in this case are equivalent to those of the enhancer and the altered c-*myc* promoters in Manca cell DNA (see Fig. 1).

The nucleotide sequence of a portion of the J_H–C_μ region of the human germ-line clone pH18-CL-10 was determined and compared with that of the corresponding region of mouse DNA (Fig. 5), which contains the enhancer core sequences[30] which are common to enhancers so far defined. Core-like sequences are present in the human DNA: there is a 67% matching between the 140 bp of mouse DNA that contains most, if not all, of the murine enhancing activity and the corresponding human sequence. The similarity between the mouse and human sequences throughout the region shown in Fig. 5 is sufficiently strong to allow a unique alignment, with several insertions and deletions.

Activation of c-*myc* transcription

To begin to investigate whether the high level of c-*myc* transcription in Manca cells was due to proximity to the immunoglobulin

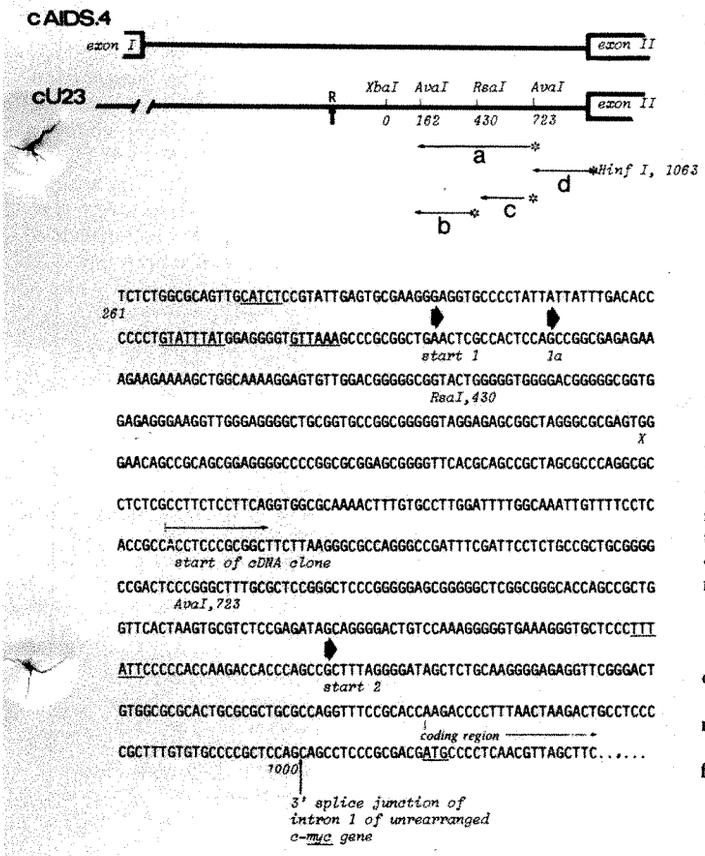

Fig. 3 Shows the nucleotide sequence from intron I of the germ-line c-*myc* gene that contains the initiation sites of the transcripts of the translocated c-*myc* gene. The recombination site of the translocated Manca chromosome is 336 nucleotides 5′ of the start of the sequence shown. Exon II of the germ-line c-*myc* gene starts at nucleotide 1,000. The transcription initiation sites (1, 1a and 2), as deduced by S_1 and primer extension analyses, are marked by the thick arrows. The probes used in these analyses (a–d, a and b being those used in Fig. 2) are shown near the top of the figure. The asterisks mark the ^{32}P-labelled ends of the probes. Underlined sequences are similar to those commonly found 5′ of RNA polymerase II-transcribed genes[27]. The initiator ATG codon of the protein encoded by c-*myc* is also underlined. X is an S_1-sensitive site, and R the recombination site. The sequence data derive from ref. 25 plus our own data in the regions of designated promoters.

Table 1 Transformation efficiency of pSV2.gpt and derivative plasmids

Plasmid	Frequency of transformation to gpt$^+$ phenotype	
	J558L cells*	rat-2 cells†
pSV2.gpt	1×10^{-4}	5×10^{-3}
pSV2.gpt.Xa‡	6×10^{-4}	ND
pSER	5×10^{-6}	ND
pSER.Xa‡	8×10^{-4}	1×10^{-5}
pSER.Xb‡	8×10^{-4}	1×10^{-5}
pSER.Ra§	8×10^{-6}	ND
pSER.Alu.a‖	2×10^{-4}	ND
pSER.Alu.z‖	5×10^{-6}	ND

Escherichia coli cells containing the above-mentioned plasmids were converted to spheroplasts[39], and fused[2] to recipient cells (10^{10} spheroplasts per 2×10^6 cells), after which the cells were plated at 5×10^3 (J558L) cells per well or 1×10^5 (rat-2) cells per culture dish. The selective medium, which contained xanthine (250 μg ml^{-1}), hypoxanthine (15 μg ml^{-1}) and mycophenolic acid (6.5 μg ml^{-1}), was added 48 h after fusion, and colonies were counted after 14 days. The experiments were routinely repeated three times. ND, not done.

* A mouse plasmacytoma cell line.

† A rodent fibroblast cell line.

‡ Xa/Xb plasmids contain an insertion in either orientation (a or b) of the 2.2 kb *Xba*I fragment from cU23.

§ pSER.Ra contains an insertion of a 4 kb *Eco*RI fragment from the mouse immunoglobulin heavy-chain C_α gene.

‖ Alu.a/Alu.z plasmids contain an insertion of either of two *Alu*I fragments (a and z) derived from the 2.2 kb *Xba*I fragment.

heavy-chain locus enhancer, the transcription of the translocated c-*myc* gene was studied in a murine myeloma cell line, J558L. The myeloma cells were transformed by spheroplast fusion with either of two plasmids, pSV.26 or pSV2.Δ4. Plasmid pSV2.26 contains the 11.7 kb *Eco*RI fragment from cU23 (containing the translocated c-*myc* gene plus about 8 kb of 5′ flanking sequences which include the immunoglobulin heavy-chain locus enhancer, see Fig. 1) the translocated c-*myc* gene cloned into the *Eco*RI site of pSV2gpt. Plasmid pSV2Δ4 contains a 9.5 kb *Eco*RI fragment (derived from the 11.7 kb *Eco*RI fragment of cU23 by deletion of the central 2.2 kb *Xba*I fragment) cloned into the *Eco*RI site of pSV2.gpt. Plasmid pSV2Δ4 thus lacks the sequences identified above as having transcriptional enhancing activity.

After transforming with these plasmids, gpt$^+$ transformants of J558L cells were isolated and assessed for the presence of exogenous DNA. Clones 26.1–26.9 were nine cloned isolates of cells transformed by pSV2.26; Δ4.2 is a cell line developed after transformation with pSV2.Δ4; Δ4.1 is a pool of several colonies transformed by pSV2.Δ4. Most cells transformed by pSV2.26 have acquired only single or a few copies of the exogenous DNA, and in most of these cases the integration has occurred within the 11.7 kb *Eco*RI fragment, so that *Eco*RI fragments smaller than 11.7 kb are detected with the c-*myc* probe[31]. Analysis with enzymes that cut within this fragment, however, indicate that in at least four out of nine cases (clones 26.1, 26.2, 26.4 and 26.7) contiguous DNA sequences that extend from the enhancer through the transcriptional initiation sites mapped above, and into the truncated c-*myc* gene, are intact (Fig. 6).

By contrast, the cells transformed in identical conditions by pSV2.Δ4, contain multiple, tandem copies of the exogenous DNA, and in each case the c-*myc* transcription unit and upstream sequences are intact. This difference in copy number of transforming DNA in cells selected for gpt$^+$ phenotype may be due to a positive effect (from over 7 kb away) of the enhancer on *Ecogpt* transcription: in the absence of the enhancer, high levels of *Ecogpt* transcription may only be obtained from an increased copy number. Consistent with this, the transformation frequency of J558L cells by pSV2Δ4 is 5–10-fold lower than the frequency of transformation by pSV2.26 (data not shown). The difference in copy number may also result from a deleterious effect of excess c-*myc* gene product on J558 cells, which already contain an actively transcribed translocated mouse c-*myc* gene[32]. If such an effect exists, and if the immunoglobulin heavy-chain locus enhancer does activate Manca cell c-*myc* transcription, then there may be a selective advantage to cells transformed with pSV2.26 that retain only one or even no intact copies of the Manca cell c-*myc* gene.

Both total and poly(A)$^+$ RNA were isolated from groups of transformants, and were analysed by Northern transfer and hybridization to probe 1 (see Fig. 1). Although transformants receiving pSV2.Δ4 contained multiple intact copies of the transfected c-*myc* gene, none of them showed evidence for much c-*myc* transcription over and above the level of the mouse c-*myc* transcription endogenous to J558L cells (data not shown). By contrast several lines of cells transformed by pSV2.26 showed strongly hybridizing c-*myc* transcripts (data not shown).

Because of the variability in retention of c-*myc* DNA sequences, and the cross-reactivity of the Northern probe with the mouse c-*myc* transcripts in J558L cells, a quantitative com-

parison of human translocated c-*myc* gene transcription was better made by S_1 nuclease mapping. The S_1 probe a (Fig. 3), which detects the major initiation site, was protected to a similar quantitative degree by Manca cell RNA and by RNA of several lines transformed by pSV2.26 (for example, lines 26.1, 26.4 and 26.7, see Fig. 7). That RNA in these cell lines is qualitatively the same as in Manca cells was further indicated by use of S_1 probe b. Use of either probe shows almost no protection by RNA of cell lines Δ4.1 or Δ4.2 (see Fig. 7) even though these cells contain multiple intact copies of the transforming DNA (Fig. 6). It cannot be argued that in either of these cases the transforming DNA has become sequestered in a transcriptionally inactive area, since continual selection for *Ecogpt* gene activity is made. In addition, several isolates of both total and poly(A)$^+$ RNA from these cells gave the same result, and these RNAs were positive in an S_1 nuclease protection assay of *Ecogpt* transcripts (data not shown). It appears then, that the activity of the major transcriptional initiation site for translocated c-*myc* gene transcription is severely reduced by deletion of sequences 360 bp upstream of it. Deletions at this distance upstream of a

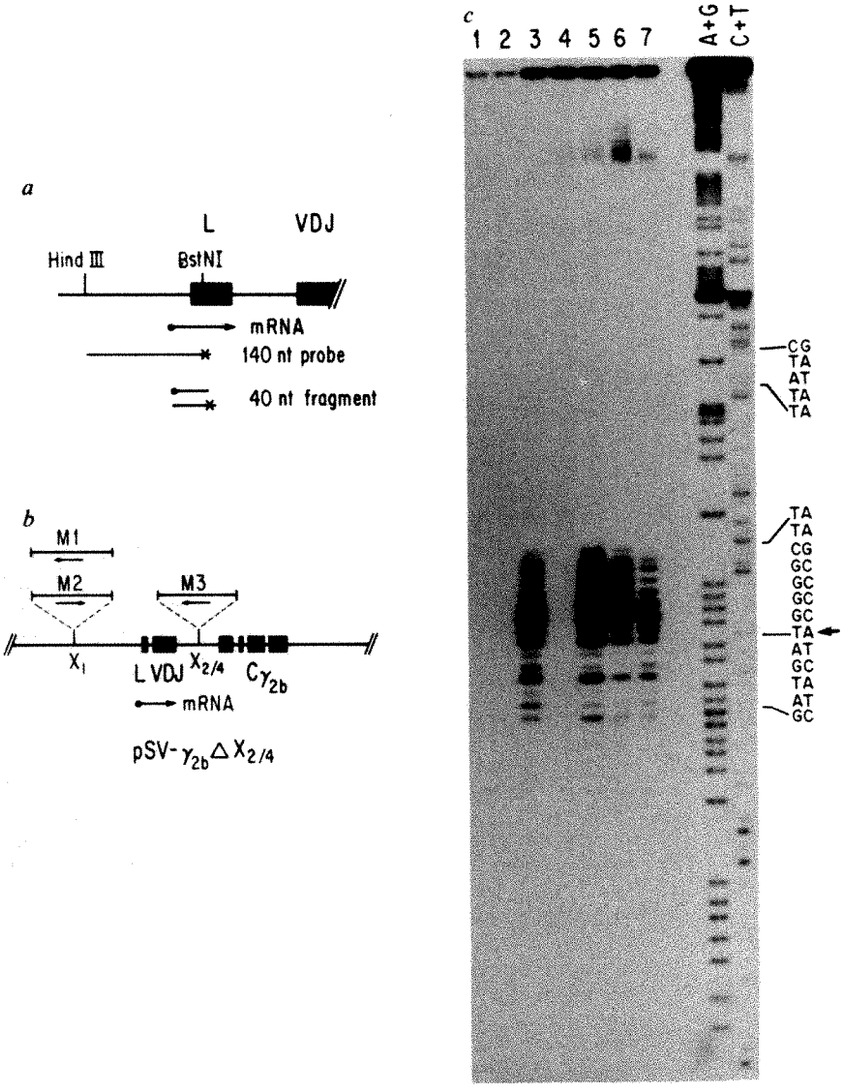

Fig. 4 *a*, Strategy of the S_1 nuclease mapping experiment shown in *c*. The probe is an end-labelled *Hin*dIII–*Bst*NI fragment, which was strand separated and annealed to total cell mRNA before S_1 digestion and electrophoretic resolution, which were carried out as described previously[23,24]. The 40 bp fragment protected by correctly initiated γ26 mRNA is as predicted by primer extension analysis[44]. The solid blocks indicate the leader (*L*) exon and 5′ end of the *V–D–J* exons. ***b*** Shows the derivatives of pSV-γ2bΔ$X_{2/4}$ used for transfection. The 2.2 kb *Xba*I fragment into the X_1 (M1 and M2) or $X_{2/4}$ (M3) sites[2] in the indicated orientations. ***c*** Shows the S_1 nuclease resistant hybrids formed between the probe shown in *a* and: lane 1, 20 μg tRNA; lane 2, 20 μg RNA from J558L cells; lanes 3–7, 20 μg RNA from J558L cells transfected with: lane 3, pSV-γ2bVC[2]; lane 4, pSV-γ2bΔ$X_{2/4}$; lane 5, pSV-γ2bΔ$X_{2/4}$ M1; lane 6, pSV-γ2bΔ$X_{2/4}$ M2; lane 7, pSV-γ2bΔ$X_{2/4}$ M3. In the two right-hand lanes are co-electrophoresed sequencing reactions[34] of the probe, which allow the identification of the transcription initiation site (arrow) and the GATAA box at position −30.

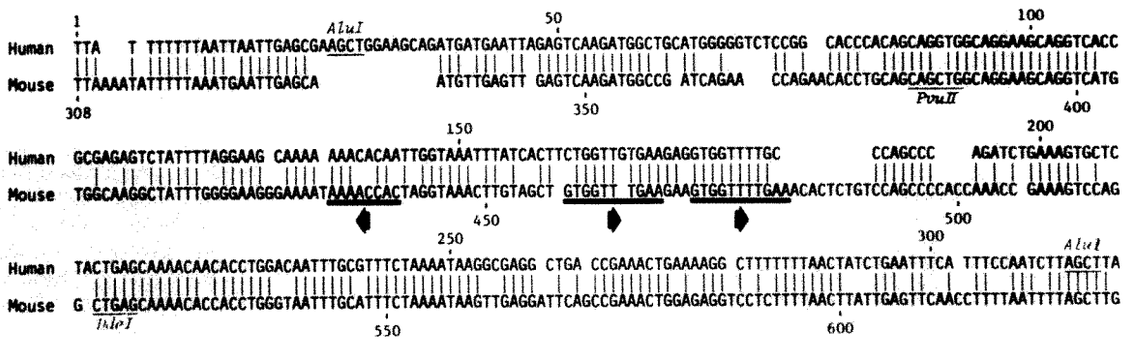

Fig. 5 Sequences of the murine[2] and human enhancer elements, which were compared using the SEQ computer program[45].

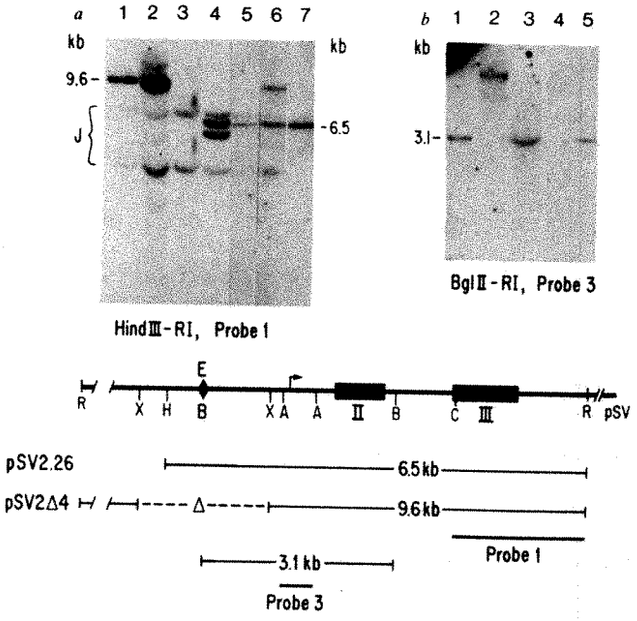

Fig. 6 Southern blot analyses of c-*myc* containing sequences in J558L cells, and in their derivatives transformed with either pSV2.26 or pSV2.Δ4. ***a*** Shows a blot obtained using probe 1 (as indicated in the diagram below) and *Hin*dIII plus *Eco*RI digested DNA from: lane 1, Δ4.2 cells; lane 2, Δ4.1 cells; lane 3, J558L cells; lane 4, 26.7 cells; lane 5, 26.2 cells; lane 6, 26.1 cells; lane 7, 5 pg of pSV2.26 cleaved with *Hin*dIII plus *Eco*RI, co-electrophoresed as a marker, ***b*** Shows a blot obtained using probe 3 and *Bgl*II plus *Eco*RI cleaved DNA from: lane 1, 26.1 cells; lane 2, 26.5 cells; lane 3, 26.4 cells; lane 4, J558L cells; lane 5, as in lane 7 of *a*, but cut with *Bgl*II. The diagram below the blots shows the 11.7 kb *Eco*RI fragment contained in pSV2.26 and also the position of the 6.5 kb *Hin*dIII–*Eco*RI fragment. The deletion (Δ) in pSV2Δ4 removes the *Hin*dIII site, as a result of which a 9.6 kb *Eco*RI fragment is the *Hin*dIII plus *Eco*RI digestion product that hybridizes to the c-*myc* probe. As a further result of this deletion the 3.1 kb *Bgl*II fragment detected with probe 3 (indicated in *b*) is only detected in pSV2.26 transformants. Bands labelled J in *a* are due to the cross-reactivity of probe 1 with normal and rearranged mouse c-*myc* genes in J558L cells[11,32]. Restriction sites marked in the lower diagram: R, *Eco*RI; X, *Xba*I; H, *Hin*dIII; B, *Bgl*II; A, *Ava*I; C, *Cla*I.

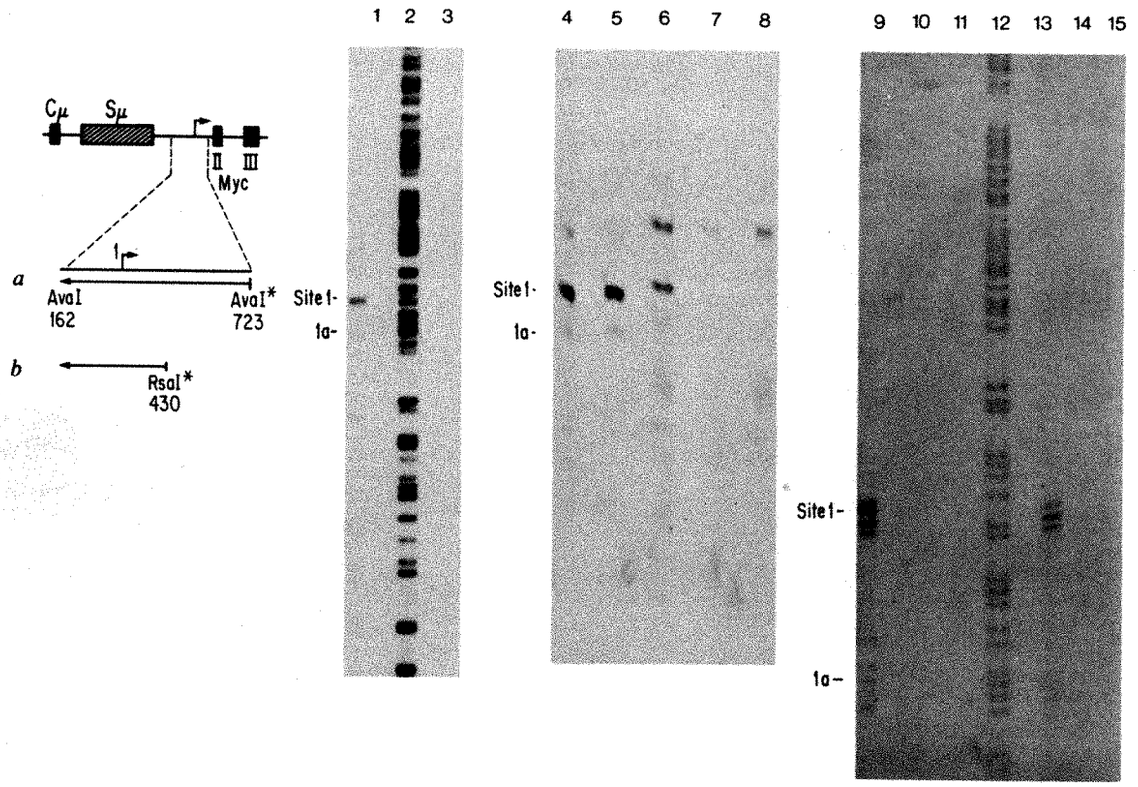

Fig. 7 S_1 nuclease analysis of mRNA from Manca cells, J558L cells, and transformed derivatives of J558L cells. Lanes 1–8 were reactions involving probe a, and lanes 9–15 involved probe b. Lane 2 is a pyrimidine sequencing reaction of probe a, and lane 12 is a similar reaction with probe b. The other lanes are the S_1 reactions, with mRNA from: lane 1, 26.7 cells; lane 3, J558L cells; lane 4, 26.1 cells; lane 5, 26.4 cells; lane 6, Manca cells; lane 7, Δ4.1 cells; lane 8, yeast cells; lane 9, Manca cells; lane 10, 26.3 cells (which retained no human c-*myc* sequences); lane 11, Δ4.1 cells; lane 13, 26.1 cells; lane 14, Δ4.2 cells; lane 15, J558L cells. The end-labelled, strand-separated[41] probes were melted at 85 °C, then annealed to the RNAs at 51 °C for probe a, and at 30 °C for 12 h for probe b. S_1 digestions were carried out at 15 °C for 2 h. Electrophoresis was carried out as described previously, for lanes 1–8 on a 6% gel run for 7 h, for lanes 9–15 on an 8% gel run for 3 h. All reactions contained equal amounts of sample RNA made up to 20 μg with yeast RNA. S_1 nuclease-sensitive sites specific for the presence of lymphoid RNA are indicated.

promoter are characteristic of enhancer mutations[33]. As the enhancing activity of the deleted fragment has been demonstrated and largely localized to one fragment (the *Alu* 'a' fragment), it appears likely that it is the removal of the immunoglobulin heavy-chain locus enhancer that has drastically reduced transcription of the translocated c-*myc* gene.

Multiple mechanisms of c-*myc* activation

We show here that Manca cells contain a translocated c-*myc* gene that is transcribed from previously cryptic start sites that ordinarily form part of intron I of the c-*myc* gene. This transcription is reproduced with fidelity after introduction of the gene into mouse myeloma cells. Use of this system has allowed us to demonstrate that transcription from at least the major cryptic promoter is dramatically dependent on the presence of sequences over 350 bp upstream of the RNA initiation site. These sequences include an element that we demonstrate to be a human immunoglobulin gene-associated enhancer element, and it may be this element itself that is responsible for activating translocated c-*myc* transcription in Manca cells. The remaining possibility, that it was the removal of other sequences (including about 300 bp of DNA that are also ordinarily part of c-*myc* intron I) that drastically reduced transcription from initiation site I is presently being investigated. The unrearranged c-*myc* gene is still present in Manca cells, but our preliminary results from use of Northern probes (probe 2 in Fig. 1), S_1 mapping and cDNA cloning indicate that this allele is barely, if at all, expressed. Such a situation has already been reported for a mouse plasmacytoma and may be true for other Burkitt's lymphomas[11,32,34]. Hence, transcriptional activation of the c-*myc* gene appears to be an important result of translocation and in the case described here, it is possible that such activation is largely contributed to by the immunoglobulin heavy-chain locus enhancer.

The retention of the immunoglobulin associated enhancer element adjacent to the translocated c-*myc* gene is not a common feature of c-*myc* translocations so far documented in either mouse[7,10,11,35] or man[12,36]. In these instances, the translocated gene is still transcribed[7,10,11,37], whilst again the untranslocated gene may be silent[11,32,34]. In these cases, transcription of the translocated c-*myc* gene may be maintained by a cellular enhancer-type element yet to be identified, and which may be a considerable distance from the translocated c-*myc* gene.

Alternatively, translocated c-*myc* genes may not be directly dependent upon immunoglobulin sequences for their transcription, but rather their transcription may be activated by the accumulation of mutations in regulatory regions. For example it has been suggested[34] that the c-*myc* gene product itself may regulate its own transcription, and that, in lymphomas harbouring translocated genes, the translocated but not the normal c-*myc* gene, escapes this repression. At this stage, the hypothesis of positive activation, and that of escaping repression, are not mutually exclusive.

The detachment of c-*myc* exon I sequences from c-*myc* exons II and III is a consequence for all BALB/c and for several human c-*myc* translocations thus far documented[7,10–12,38]. We have previously suggested[22,31] that this event, in itself, leads to increased translation of c-*myc* RNA in cells harbouring such translocations.

In summary, there are probably multiple steps in the activation of the human c-*myc* gene in non-Hodgkin's lymphomas. From this article it is clear that previously cryptic promoters of the c-*myc* gene are activated upon translocation, and that this activation is dependent upon upstream sequences. In Manca cells, the critical element in these upstream sequences may be the human immunoglobulin heavy-chain locus enhancer element. As both the translocated c-*myc* gene from a mouse plasmacytoma and the translocated human c-*myc* gene from Manca cells have detectable biological activity (ref. 46 and our unpublished data) it is apparent that the activation of the c-*myc* gene contributes to either initiation or maintenance of oncogenesis. It is possible that the misuse of a developmentally regulated, cellular enhancer element will be found, in many cases, to be responsible for activating oncogenes.

We thank Lena Angman, John McMaster, Anne Maxwell and Eleanor Basel for their help, and P. Jat for advice concerning S_1 analysis, C. M. Croce for the gift of pH18-cl-10, W. Topp for the kind distribution of rat-2 cells, and B. Clarkson for Manca cells. A.C.H. and K.W. thank ICRF and EMBO respectively for travel and long term fellowships. The work was supported by NIH grants AI-17879 (to S.T.), CA-14051 (a core grant to S. Luria), and CA-34502 (W.H.).

Note added in proof: The integrity of all RNA preparations has been confirmed by succcessful S_1 analysis of gpt transcription.

A lower limit for the mass of the compact object in SS433—a black hole?

The SS433 system ejects two relativistic jets with a velocity of 0.26c. The two jets are in oppsite directions, precessing with a period of 160 days[1]. The system is assumed to include a compact object which rotates around a normal star with a period of 13 days[2,3]. There are strong indications for the presence of an accretion disk around the compact object[4]. Based on study of a photometric light curve obtained during 3 years of observations[5], we suggest here that the compact object might be a black hole.

The photometric characteristics of SS433 have been studied extensively in the past few years[4–12]. Despite the erratic photometric stellar behaviour, a 13 day and 160 day periodicities have been clearly detected (refs 4–12 and 5, 10–12 respectively). The averaged 13-day light curve is highly structural and varies with the 160-day period[4,5,8–10]. However, in one third of the 160-day cycle, when the jets inclination is minimal, the averaged binary light curve is much more smooth and symmetric[5]. This light curve is reproduced in Fig. 1, where one can notice two symmetrical eclipses separated by a 'plateau', very similar to an Algol type light curve observed in many binary systems. This familiar character of the binary light curve has also been recognized by other investigators[9].

If one assumes that Fig. 1 is an Algol-type light curve not only in form but also in essence, that is, it does indeed represent the mutual occultation of two light sources[13], this curve can be used to estimate the mass ratio of the binary system[14]. We considered a system with two components: an accretion disk and a 'normal' star. These two objects are necessary parts of many models of SS433 [5,11,15–18].

In this work we used the following assumptions: (1) The primary minimum is due to the occultation of the disk by the normal star. (2) The binary plane of motion is orthogonal to the precession axis of the jets. (3) The normal to the disk is orientated at the instantaneous jet direction. (4) The normal star fills its critical lobe. (5) The disk is planar.

Consulting Fig. 1, we further assume that: (6) The eclipse of the disk is not total. (7) The width of the disk eclipse is $0.30 \pm 0.02P$, where P is the binary period.

A computer program to calculate the relative occulted area of the disk, with a given radius R_d and orientation, has been coded, using a Roche lobe geometry [assumption (4)]. This geometry is determined by the mass ratio

$$q = M_{\text{normal}} / M_{\text{compact}}$$

where M_{normal} and M_{compact} are the masses of the normal object and the compact star, respectively.

The precessional model for the jets yields $i = 79°$ and $\theta = 20°$, where i is the binary inclination [assumption (2)] and θ is the precessional angle[1]. We use these values for determining our line of sight and the disk orientation [assumption (3)]. For the particular 160-day phase section studied here we assume that the normal to the disk is in the plane which contains the normal to the binary orbital plane and our line of signt. Our numerical results, drawn at the q,R_d plane, are depicted in Fig. 2. Curve a represents the values for which the eclipse width is 0.3 of the binary period P. The dashed line above [under] curve a stands for eclipse width of $0.32P$ [$0.28P$], according to our error estimate. Curve b of Fig. 2 represents the points in which a total eclipse is attained just at mid eclipse. For the points in the domain above curve b, with larger R_d the eclipse is not total. The two constraints together yield

$$q \leq 2.3 \tag{1}$$

To estimate the masses of the two components we further assume that the radial velocity curve of the He II emission line[19] represents the orbital motion of the compact object. Crampton and Hutchings[19] best value for the amplitude of the radial velocity curve is:

$$K = 195 \text{ km s}^{-1} \tag{2}$$

and they put a lower limit of 150 km s^{-1} for this parameter. In Fig. 3, equations (1) and (2) and the lower limit for K have been used to exclude certain domains in the (M_{compact}, M_{normal}) plane. We get

$$M_{\text{compact}} \geq 4.3\ M_\odot$$
$$M_{\text{normal}} \geq 10\ M_\odot \tag{3}$$

All seven assumptions mentioned above are necessary for deriving equation (1). Consider, for example, assumptions (1)–(3). No solid proof can be found for their validity, and other competing assumptions[20,21] cannot be excluded. However, as assumptions (1)–(3) seem to be consistent with the spectroscopic and photometric characteristics of the system, and as they are a necessary part of the 'precessing disk' model[16], these assumptions are adopted here. Assumption (4), on the other hand, is not necessarily essential for all precessing disk models. However, the large mass accretion rate[17], the indication for a stream[8,19] and for a hot spot[5] in the system, all suggest that the mass transfer is through an L_1 overflow[17]. This implies that the normal star fills its critical lobe[17,18] and hence our assumption (4).

Assumption (5) is certainly only an approximation; however, our results would be modified only slightly if the disk structure is somewhere between a planar and a spherical shape.

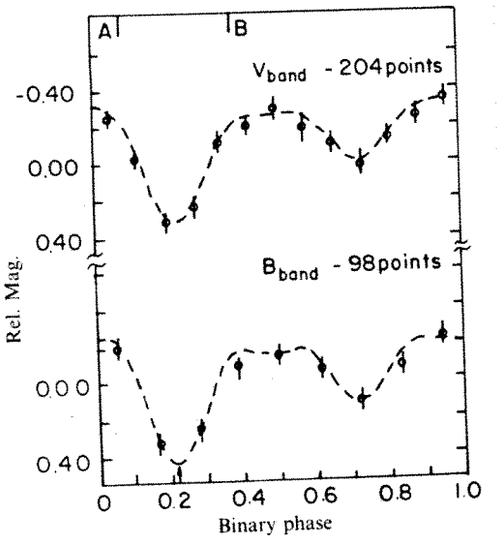

Fig. 1 A reproduction of the binary light curves in V and B bands. The plotted points are the average magnitudes in each of the corresponding bins in the phase axis. The dashed lines were obtained by a least square fitting of all the data points to a 5 term Fourier series in the basic period. The arrow indicates the phase which is a quarter of a cycle after maximum positive velocity of the He II emission lines. The phase interval ($0.3P$) between the A and B bars indicates the eclipse duration. The light curves were obtained for $0.33 \leq \Psi_{164} \leq 0.666$ where $\Psi_{164} = (\text{JD} - 2444068.5)/164$.

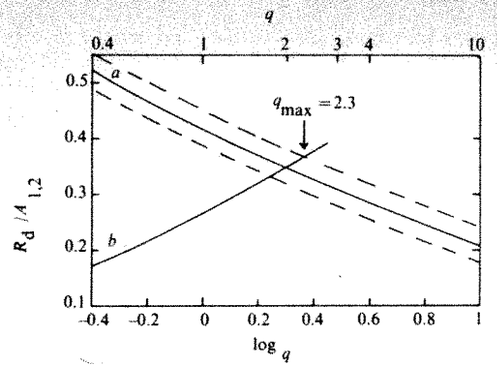

Fig. 2 The constraints on the disk radius R_d, in units of the binary separation $A_{1,2}$ as a function of q, the mass ratio.

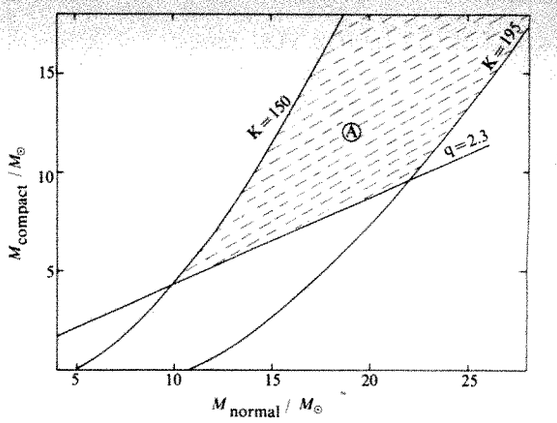

Fig. 3 The constraints on the masses of the two components. A is the allowed domain.

There are several indications that the disk eclipse is not total [assumption (6)]. First, the continuous curves of Fig. 1, which have been adopted to represent the averaged light curves in V and B[5], do not include a flat constant minimum of any length. Secondly, the HeII line appears through the whole binary period, even during mid eclipse[19]. It implies that the source of this emission line (centre of disk, disk's corona?) is not totally eclipsed. As the He II line is probably generated close to the centre of the disk and not at its edge, its appearance during mid eclipse is a strong evidence against the total eclipse hypothesis. Thirdly, the intensity at minimum is larger than half the total luminosity while the disk apparently contributes more than half of the total intensity in V and B[8]. All these arguments make assumption (6) very attractive. We assume, therefore, that if the disk radius is R_d, at least one point on the disk central plane at distance R_d from its center is not occulted. According to this assumption the disk thickness[11,16] did not enter our calculations. The assumption (7) value has been deduced from Fig. 1 and the errors represent our eye estimate.

Our derived constraints on the masses [equation (3)] depend on K to the third power, therefore our conclusion is very sensitive to its exact value. Indeed, Crampton and Hutchings[19] considered the possibility that their value for K does not represent the true orbital motion of the compact object. They estimate the value of 150 km s^{-1} as the lower limit for K when effects that produce spurious high amplitude are taken into account. One important effect of this kind is a partial eclipse of the disk during the phase of maximum radial velocity. The fact that the length of the disk eclipse is less than $0.32P$ significantly smaller than 0.5, excludes this effect in our case. We therefore consider the lower limit for K as real.

The two curves of Fig. 2 were obtained by using a Roche geometry, assuming corotation and alignment of the normal star. However, several works[5,18] suggested that this might not be the case, and therefore the geometry is somewhat different[22,23]. Consider, for example, the case in which $\Omega = \omega_{stellar}/\omega_{orbital} = 1.4$, where $\omega_{stellar}$ and $\omega_{orbital}$ are the rotational frequencies of the normal star and the orbital motion, respectively. In such a case, the upper limit for q should be 3, and the lower limit for $M_{compact}$ would be $3M_\odot$. With $\Omega = 2$, the implied mass of the compact object is $1.5M_\odot$. The last pair of values is, however, very unlikely if one assumes that the basic precession is generated by tidal forces exerted on the normal star. Calculations by Hut and van den Heuvel[18] show that with $\Omega \geq 1.4$ and $M_{compact} = 1.5M_\odot$, a 13d orbital period and a 160d precessional period cannot be accounted for. One can also argue that the possible non-alignment of the star is relatively small ($\sim 20°$) and therefore it will modify our results only slightly[24]. We therefore regard equations 1 and 3 as realistic limits.

An interpretation of the entire light curve of SS433 requires a detailed geometrical and physical model for the system which should include many parameters. In particular the relative intensity of the different sources in the system and the distribution of their surface brightness should be incorporated in such a model. Indeed, such an interpretation is attempted by one of us[25] (E.M.L.) in a separate work, in which a theoretical synthetic light curve is fitted to all the available photometric data. For this purpose Leibowitz[25] assumes a hot spot as an additional source of light characterized by a very special radiation pattern. He also assumes a uniform surface brightness over the disk and neglects limb darkening of the normal star. Our approach, on the other hand, is to analyse a smooth and simple section of the light curve, without introducing any further assumptions or parameters other than those used in the most basic and common precessing disk models. Here we have considered only the disk radius and the mass ratio as free parameters. Despite the difference in approach and in the analyzing technique and despite the many more parameters in Leibowitz's model, his findings are consistent with this work.

Our basic and simple picture has yielded a most likely lower limit of $4.3\,M_\odot$ for the compact object, (equation (3)). This limit is much larger than the mass of the most massive neutron star observed so far[26]. It is also larger than most theoretical upper limits for this value[26]. We therefore conclude, that it is tentatively reasonable to assume a black hole for the compact object of SS433. Further photometric and spectroscopic observations in SS433 are clearly required in order to reaffirm our conclusion and in order to improve the constraints on the mass of the compact object in this system.

We thank M. Milgrom for helpful discussions and N. Brosch, A. Fabian, D. Gies, K. Horne, J. Matese, J. Refaeli, E. van den Heuvel and D. Whitmore for many useful comments.

Continuing formation of the central star cluster in M87

A. C. Fabian*, H. Itoh†, G. C. Stewart*, C. R. Canizares‡ & P. E. J. Nulsen*

* Institute of Astronomy, Madingley Road, Cambridge CB3 0HA, UK

The rising velocity dispersion of the stars in the neighbourhood of the central luminosity spike observed[1–3] in the elliptical radio galaxy M87 was originally considered to be evidence for the presence of a massive black hole[4] ($M \sim 5\times10^9 M_\odot$). A later spectrum[3] taken in good seeing, however, shows that most of the light in the spike is due to stars, which restricts any black hole model; the luminosity spike may be a star cluster formed from gas infalling from the outer regions of M87[5,6]. Our analysis[7] of Einstein Observatory X-ray data on M87 revealed a cooling inflow of gas occurring at the rate required to build such a cluster. We show here that the back-reaction on the flow of the nuclear luminosity is small unless M87 was much brighter in the past and we suggest that massive central star clusters may be common in the central galaxies in many clusters and, on a smaller scale, in many elliptical galaxies.

X-ray continuum[5,8] and emission line[5,9,10] measurements of the temperature of the gas in M87 have established the presence of a temperature gradient which implies that the gas is cooling and accreting onto the galaxy[11–14]. We have combined these spectral and imaging[15] data to determine in detail the gas temperature and density profiles and thence the mass flow rate, $\dot{M}$, at each radius[7]. $\dot{M}$ drops from 10 $M_\odot\,yr^{-1}$ beyond about 50 kpc to $\sim$1 $M_\odot\,yr^{-1}$ at 750 pc, or 10 arc s, from the nucleus. At this inner radius, which is determined by the quality of the data, the gas temperature, T, is $\sim10^7$ K. It must fall steeply at some point within this region, liberating an X-ray luminosity $\sim 5/2\,\dot{M}/\mu m_H\,kT$, where μm_H is the mean mass per particle. We have identified this luminosity with the 2–3 arc s extended X-ray source[16] that coincides with the central luminosity spike. Gas is thus cooling and collapsing there at a rate of $\sim1\,M_\odot\,yr^{-1}$ and we presume that most of it forms stars. Up to $\sim10^{10}\,M_\odot$ is added over the age of the galaxy if the flow is steady. The high pressure in a cooling flow ($\sim10^6$ cm^{-3} K) leads to the formation of low mass stars[17,18] and we therefore expect the star cluster so formed to have a large ratio of mass to luminosity ($M/L > 10$). The optical colours[1] are consistent with the models of Sarazin and O'Connell[18].

The optical jet in M87 is evidence for activity in the nucleus and we therefore consider the possible influence of nuclear luminosity on the cooling flow. The flow itself would provide sufficient matter to power even a bright quasar if it were accreted by a compact object. The ionization equilibrium of gas in a cooling flow was calculated numerically by iterating the effects of photo-absorption and collisional ionization due to X-rays from the gas as well as from a nuclear X-ray source ΔL. The important bound–bound, bound–free and free–free radiative processes above 10^6 K of H, C, N, O, S, Si and Fe were included in the calculations. The density and temperature of successive radial shells of gas were interpolated from our solution[7] and extrapolated into the centre assuming constant pressure and $\dot{M}$. The results below are quoted for a radius of 190 pc, which is within the core of M87.

Departures from collisional equilibrium alone are small (less than a factor of 2) for the dominant ions of C, N, O and Fe provided that the $\Delta L_{41} < 10$, where $\Delta L = \Delta L_{41}\times10^{41}$ erg s^{-1} in the 0.5–4.5 keV range (an energy index of 0.75 was used). Radiation pressure is negligible in any reasonable distribution of mass in the core of M87 provided that $\Delta L_{41} < 10^5$. The local heating rate due to photoabsorption and to Compton interactions is found to exceed the local cooling rate in our calculations when $\Delta L_{41} > 10^2$. The cooling flow should be strongly disrupted above that luminosity. The observations[17] indicate $\Delta L_{41} < 4$, which means that the core of M87 must brighten considerably before the cooling flow is stopped. (Increasing $\dot{M}$ does, of course, increase the limits on ΔL.) The smooth X-ray surface brightness profile is observational evidence that the flow has lasted for times comparable with a typical cooling time of $\leqslant10^9$ yr.

Cooling flows are relatively common in clusters surrounding a single cD galaxy[19,20] and we may expect that some of the inferred 5–500 $M_\odot\,yr^{-1}$ of accreting gas forms central star clusters in them. We have re-analysed the X-ray surface brightness profile[21] of NGC1275 in the Perseus cluster to determine $\dot{M}(r)$ within a reasonable gravitational potential. Once again, we find that $\dot{M}$ increases with radius, r, up to 400 $M_\odot\,yr^{-1}$ at 100 kpc and that $\sim40\,M_\odot\,yr^{-1}$ passes into the inner 10 kpc (our best resolution) of the galaxy. It appears that the stars form over a large range of radii, comparable with the extent of the optical filaments[22], and by analogy with M87, it is likely that NGC1275 contains a large star cluster in its core. Scaled-down versions of the flows in M87 and NGC1275 may occur in many elliptical galaxies[23] and could also take place in the bulges of spiral galaxies. The centre of M31 may possibly contain a cluster of low mass stars (ref. 24; but see 25). The evolution of the densest core of a large central star cluster may in turn be related to the nuclear activity seen in many galaxies. Gravitational accretion by any central mass takes place from a hot (10^6–10^7 K) medium.

We thank R. Terlevich for discussion and S. Inagaki for a preprint. A.C.F. acknowledges support from the Royal Society.

Mystery cloud of AD 536

R. B. Stothers

Institute for Space Studies, NASA Goddard Space Flight Center, 2880 Broadway, New York, New York 10025, USA

Dry fogs appear in the atmosphere when large volcanic eruptions inject massive quantities of fine silicate ash and aerosol-forming sulphur gases into the troposphere and stratosphere. Although the ash gravitationally settles out within weeks, the aerosols spread around the globe and can remain suspended in the stratosphere for years. Because solar radiation is easily absorbed and backscattered by the volcanic particles, a haziness in the sky and a dimming of the Sun and Moon are produced. Very dense and widespread dry fogs occur, on the average, once every few centuries[1–3]. The sizes and intensities of some of the largest of them before the modern scientific era have been estimated by several indirect methods[2,4,5]. The densest and most persistent dry fog on record was observed in Europe and the Middle East during AD 536 and 537. Despite the earliness of the date, there is sufficient detailed information to estimate the optical depth and mass of this remarkable stratospheric dust cloud. The importance of this cloud resides in the fact that its mass and its climatic consequences appear to exceed those of any other volcanic cloud observed during the past three millenia. Although the volcano responsible remains a mystery, a tropical location (perhaps the volcano Rabaul on the island of New Britain, Papua New Guinea) can be tentatively inferred.

Four reliable contemporary descriptions of the sky conditions in AD 536–537 exist[6]. Procopius[7], a Byzantine historian who lived in Rome (42° N) at the time, wrote that "the Sun gave forth its light without brightness, like the Moon, during this whole year, and it seemed exceedingly like the Sun in eclipse, for the beams it shed were not clear nor such as it is accustomed to shed... and it was the time when Justinian was in the tenth year of his reign". From Constantinople (41° N) Lydus[8] observed that "the Sun became dim in the course of the recently passed fourteenth indiction, for nearly a whole year, when Belisarius had the highest honour, so that the fruits were killed at an unseasonable time". An anonymous chronicler (associated by tradition with the name of Zacharias of Mytilene[9]) also referred to observations made from Constantinople in the following terms: "in the year fourteen... the Sun began to be darkened by day and the Moon by night... from the 24th of March in this year till the 24th of June in the following year fifteen". According to another contemporary writer (probably John of Ephesus), describing conditions in Mesopotamia (30–37° N) and later quoted by Michael the Syrian[10] and Bar-Hebraeus[11]: "in the year 848 of the Greeks... the Sun was dark and its darkness lasted for eighteen months; each day it shone for about four hours, and still this light was only a feeble shadow... the fruits did not ripen and the wine tasted like sour grapes".

What can be made of such astonishing reports? In ordinary conditions, the Sun's radiance would appear perceptibly diminished only if the Sun lay less than ~2.5° in apparent altitude above the horizon[12]. The normal visual extinction at apparent zenith angle $z = 87.5°$ is 3.4 mag (astronomical magnitudes)[13]. If the Sun shone for only 4 hours a day at a latitude of 33° N during the fruit-growing season (spring and summer) of AD 536, then it must have begun setting at $z \sim 30°$. The total visual extinction produced by the atmosphere in combination with the volcanic dust can be adequately represented by Bouguer's law[14]; in the present case

$$[(\Delta m)_0^D + 0.20] \sec z = 3.4$$

where $(\Delta m)_0^D$ is the zenithal volcanic dust contribution and 0.20 mag refers to the unperturbed atmosphere. It follows that $(\Delta m)_0^D \sim 2.7$ mag, corresponding to an excess optical depth $\tau_D = 0.921\,(\Delta m)_0^D \approx 2.5$. At maximum altitude both the Sun and the full Moon would have appeared ~10 times fainter than normal, which can readily explain their reported 'darkening'. Scattered sunlight, however, would still have illuminated the rest of the sky, which therefore would not have appeared as dark. Although the derived optical depth excess is rather uncertain, it can be checked below by an independent method.

What sort of volcanic eruption could have produced such a dense dust veil? Not a Mediterranean eruption[6], which would almost certainly have been mentioned by Procopius. A clue is found in the duration of the dry fog. Historically, dry fogs have always developed rather quickly, although the dates of their slow disappearances are susceptible to visual impression and have inevitably been uncertain by a few months. The dry fog of AD 536 first appeared in the Mediterranean region in late March. According to the observers at 41–42° N, it lasted 12–15 months, that is, until March–June AD 537; this period agrees in an acceptable way with the variously reported dates. At 30–37° N, however, the duration of the dry fog was 18 months. Its prolonged visibility at the more southerly latitudes suggests that the haze was significantly thicker there, and hence that the eruption which produced the aerosols was situated somewhere to the south. If so, the location was probably in the tropics (23° S–23° N) because aerosols from eruptions south of 23° S do not penetrate the Northern Hemisphere in significant amounts. Only 2 to 3 weeks would be needed for the stratospheric aerosols to reach Mediterranean latitudes. A large volcanic eruption that may be consistent with the year, March season, and possible tropical latitude of the AD 536 event was the explosion of Rabaul (4° S) on the island of New Britain, off New Guinea, which has been radiocarbon-dated to AD 540 ± 90 (ref. 15). This eruption dispersed at least 11 km^3 (bulk volume) of near-source pumice and ash, mostly to the west[16], which suggests that the March–October southeasterly monsoon[17] was blowing at the time. (Most of the distal ash would have fallen into the Bismarck Sea, and could greatly exceed in volume the near-source ejecta.)

A major tropical eruption in AD 536 would also be expected to deposit sulphuric acid aerosols on the polar ice caps, where they would remain preserved in compacted annual snow layers. A very high sulphuric acid signal has in fact been detected in a Greenland ice core by Hammer *et al.*[5], who assigned a date of AD 540 ± 10, and in another Greenland ice core by Herron[18], who estimated ~AD 535. There is little doubt that the acidity signal refers to the same event that produced the dry fog of AD 536, because both kinds of volcanic signal at the exceptionally high levels discussed here occur only once every few centuries on the average. The strength of this ancient volcanic signal relative to the signal obtained from the more recent eruption of another tropical volcano, Tambora (which exploded in April 1815), can be estimated as follows. Herron's data imply relative signal strengths (after subtraction of background) of 0.63 : 1.00 for the AD 536 eruption and the Eldgjá (Iceland, ~AD 934) eruption, while the data of Hammer *et al.*[5] (who did not provide the signal strength for the AD 536 eruption) imply a ratio of 1.00 : 0.37 for the Eldgjá and Tambora eruptions. It follows that the AD 536 signal exceeds that of Tambora by a factor of 1.7. As the eruption of Tambora increased the stratospheric optical depth at north-temperate latitudes in 1815 by $\tau_D = 1.3$ as derived by several methods (ref. 19), the excess stratospheric turbidity at these latitudes in AD 536 must have been $\tau_D = 1.3 \times 1.7 = 2.2$. (If Krakatoa, a tropical volcano that erupted in 1883, is used as the standard for comparison, essentially the same result is obtained.) This is consistent with the preceding result based on the ancient extinction reports, and therefore supports the idea that the eruption was a tropical one because the strength of the ice-core acidity signal depends on eruption latitude[5] and no correction for latitude has been applied here. Peak global aerosol loading of the stratosphere can be computed from the formula $M_D = 1.5 \times 10^{14}\,\tau_D$ g, which is insensitive to the adopted modal particle radius r if $0.15 \leq r \leq$

0028-0836/84/040344—02$01.00

© 1984 Macmillan Journals Ltd

0.7 μm—certainly the case for modern volcanic eruptions (ref. 19). The loading in AD 536 was therefore $\sim 3 \times 10^{14}$ g.

The AD 536 stratospheric 'mystery cloud' presumably decayed exponentially with a typical *e*-folding time of ~1 yr (ref. 19). If so, its optical depth would have dropped to less than 0.1 by November and December AD 539, when a faint cometary tail was visually sighted from Europe[7] and China[20].

Climatologically, the winter of AD 536–537 in the Middle East was an unusually severe one, attended by extraordinary snowfalls in Mesopotamia[9,21]. During the preceding summer (and possibly the following one as well), the fruits, including grapes, did not properly ripen in at least some parts of the Middle East and Europe. Historically, cold weather and poor harvests of grapes and other crops have tended to follow very large explosive volcanic eruptions[2]. The accepted reason is that volcanic dust clouds screen some of the incoming sunlight and thereby cause a reduction of the Earth's average surface temperature. Although it seems that Tambora's large eruption did not catastrophically affect the Middle Eastern growing season[22], the aerosol-producing eruption of AD 536, which was twice as large, apparently did.

I thank M. R. Rampino for useful comments.

Scattered UV solar radiation within the clouds of Venus

A. P. Ekonomov, V. I. Moroz, B. E. Moshkin, V. I. Gnedykh, Yu. M. Golovin & A. V. Crigoryev

Space Research Institute, USSR Academy of Sciences, Moscow, USSR

The spectral albedo curve of Venus shows a steep decline at wavelengths between 0.5 and 0.3 μm (refs 1–3). This is of interest since absorption of solar energy in this spectral region has a strong influence on the thermal balance of the venusian atmosphere. The nature and altitude distribution of the UV absorber have not been determined, although some candidate gases have been proposed. We report here the results of measurements carried out on the last Soviet venusian descent probe Venera-14 which suggest that the UV absorption is by aerosols above an altitude of 57 km and by gases below this level.

It has long been known that some UV absorber(s) is present in the venusian clouds. The same absorbing material seems to be responsible for both the low UV albedo and for producing the UV features on Venus. Gaseous sulphur dioxide is the obvious candidate for the absorber at wavelengths shorter than 0.32 μm (ref. 4), but the nature of the substance responsible for absorption longwards of 0.32 μm is not known. Remote sensing techniques have failed to solve this problem. Pioneer Venus results[5,6] and results from Veneras 9 and 10 (ref. 7) showed that the absorption of sunlight in the visible took place mainly in the upper cloud, which is why one of the principal goals of the Soviet Venera-14 mission was to investigate the distribution of the solar near-UV radiation within the main clouds during the descent of the probe through the atmosphere of Venus on 3 March 1982.

The UV photometer aboard Venera-14 was part of a complex optical instrument with a common angle-scanning device for the near-UV and the visible regions. The detector Ga–P/filter combination provided a bandpass of 0.06 μm at half-maximum centred at 0.37 μm with no appreciable leak beyond bandpass. The photometer had a circular field of view (FOV) with width 10° (FWHM). The instrument scanned a range of zenith angles by rotating the axis of the FOV in a vertical plane with a period of 2.5 s. (The photometer and its operating conditions are described in more detail elsewhere[8,9].)

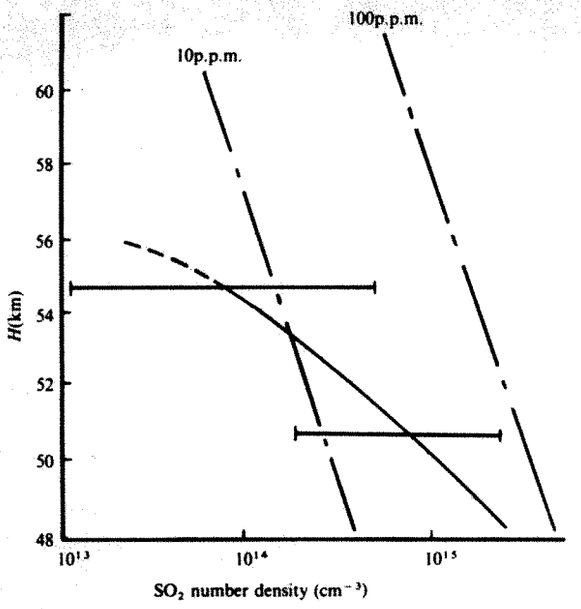

Fig. 3 Sulphur dioxide number density on the basis of the observed data on UV absorption (solid line with bars). Curves of constant mixing ratio are also shown.

The raw data from our photometric measurements as well as the results from the primary data processing are presented in Fig. 1. The data are plotted as a function of altitude (H) above the 6,052 km level. Fits by spline technique were used for least-squares approximation of the data. We define I_{45}, I_{133}, I_{164} as the solar near-UV intensities sampled at zenith angles of 45°, 133°, 164°. $F\downarrow$, $F\uparrow$, ΔF are the downward, upward and net fluxes respectively derived from intensities using the approximation:

$$I(\phi) = I(1)[a + \phi(1-a)]$$

where $I(\phi)$ denotes the angular intensity distribution, ϕ is the cosine of the zenith angle, a is the parameter derived from the least squares fit, $I(1)$ is the downwards intensity. It is a simple matter to show that:

$$F\downarrow = 2\pi I(1)\left(\frac{a}{2} + \frac{1-3}{3}\right)$$

$$F\uparrow = 2\pi I(1)\left(\frac{a}{2} - \frac{1-a}{3}\right)$$

$$\Delta F = \simeq 3(I_{45} - I_{133})$$

The data set in the uppermost portion of the profile (from 62 to 59 km) is characterized by high variability of downward intensities although the upward ones are quite stable. There was no instability of downward intensities below 59 km. Inhomogeneities 1–5 km in length are expected above 59 km which does not seem to be consistent with results obtained from remote sensing orbiters which have failed to discover inhomogeneity at scales of less than 10 km (ref. 10). The above-mentioned phenomenon may resemble the 'silver lining effect'—where the photometer views the illuminated edges of the clouds at horizontally-inhomogeneous upper layers. From about 59 km down to 48 km, the downward flux decreases gradually from 1/5th of the incident solar radiation flux at the top of the venusian atmosphere to 1/35th of this value.

Using ground-based data on the UV albedo of Venus[11] in conjunction with results from our measurements, an effective optical depth above 60 km can be estimated as $\tau_0 = \tau(1-g) \cong 3$ where τ is the optical depth, and g is the asymmetry factor of the phase function. Consequently a thick-atmosphere approximation can be obtained and all calculations may be substantially simplified. For example, altitude profiles of the volume absorption coefficient K and extinction coefficient α of the atmosphere may be derived from $(I_{45} - I_{133})$ and $(I_{45} + I_{133})$ altitude profiles[12]. The results of such an evaluation are presented in Fig. 2. Note, however, that K is extremely sensitive to computational errors which leads to some uncertainty over its value.

The altitude profile of the net flux shows that the true absorption of UV radiation is present everywhere within the cloud structure but most strongly in the upper clouds ($H > 58$ km). The next lowest layer ($58 > H > 55$ km) has the minimum UV volume absorption coefficient. These results are qualitatively consistent with the data Tomasko[6] obtained in the visible region. In the altitude interval between 55 and 48 km the absorption is probably coupled with the increasing gas density.

Figure 2 also provides a comparison between our results and the extinction coefficient from LCPS (cloud particle size spectrometer) measurements[13]. The profiles of K and $\alpha(1-g)$ presented in Fig. 2 lead to the following conclusions:

(1) There are two different absorbers which dominate above and below the 57-km level. This is supported by different altitude dependences above and below this level and the minimum-volume absorption coefficient K observed there.

(2) The most important absorber above 57 km is probably particulate matter. Particles of mode 1 as defined by Knollenberg and Hunten[13] can be identified as the absorbers near the cloud top. The sharp rise of absorption is crudely consistent with the rise in the mode-1 particle concentration above 57 km. Of course, the possibility cannot be ruled out that some absorbing gas has the same type of altitude distribution (due, for example, to some photochemical processes) but this seems unlikely. If mode-1 particles are responsible for the measured K value it is possible by combining Knollenberg and Hunten's data with ours to evaluate κ, the imaginary part of the refractive index. We find that $7\times10^{-4} < \kappa < 7\times10^{-3}$. The existing information is not yet sufficient for identification but now two additional limitations on the absorber are implied: the value of κ and the altitude distribution. Sulphur[4,14], $FeCl_3{\cdot}H_2SO_4$ (ref. 15) and $(NH_4)(S_2O_5)$ (ref. 16) have been considered recently as possible constituents. Toon *et al.*[14] have suggested that even a few per cent of strongly absorbing short-chain sulphur allotropes as particles, such as S_3 (absorption band centred near 4,000 Å) and S_4 (absorption band centred near 5,300 Å) could account for the solar energy deposition profile in the upper clouds at wavelengths longer than 0.32 μm. Our data seem to be consistent with an approximate 1–10% mass of sulphur within the upper clouds. A steep decline of absorption from the beginning of our measurements at 62 km to the minimum absorption detected at 56 km resembles a steep decline from the peak sulphur mass fraction at 58 km calculated by Toon[14] to the small amount present below 56 km. The peak value itself was not detected in our measurements but it could be masked by a mode-1 concentration growth above 58 km.

(3) Probably the most important absorber below 57 km is a gas. The basis for this proposal is the increase of K with decreasing altitude (K increases even faster than does the atmospheric number density). An attractive candidate for this gas is SO_2 which was discovered long ago as a small constituent of the venusian low atmosphere[17,18], whose concentration extrapolated to the altitude ~50 km is about what is needed to provide the observed UV absorption. Figure 3 shows a profile of SO_2 in the altitude interval 50–57 km calculated on the basis of the hypothesis that SO_2 gas is responsible for absorption.

We have used the laboratory cross-section of SO_2 taken from refs 19, 20, although our neglect of the influence of the unresolved line structure of SO_2 bands in the radiative transfer treatment[21] may necessitate a later re-evaluation of the SO_2 concentration. More details concerning results described above and their interpretation are given in ref. 9.

Analysis for rare earth elements in accessory minerals by specimen isolated secondary ion mass spectrometry

J. B. Metson, G. M. Bancroft, H. W. Nesbitt & R. G. Jonasson

Departments of Chemistry and Geology, University of Western Ontario, London, Ontario, Canada N6A 5B7

The distribution of rare earth elements (REEs) in minerals and mineral assemblages is of considerable geochemical significance. However, because of their low levels in most minerals, analysis for REEs is a considerable challenge. The application of secondary ion mass spectrometry (SIMS) to this problem has been limited by the presence of molecular ion interferences in the secondary ion mass spectrum. We describe here the application of the specimen isolation technique[1] to rare earth analysis by SIMS. The method effectively suppresses molecular ions while maintaining sufficient sensitivity to examine REE distribution in a variety of accessory minerals.

REEs have been used to help interpret the genesis of igneous rocks[2], metamorphic rocks[3] and sedimentary rocks[4], as well as the history of the Earth[5]. Their chemistry is predominantly ionic, their properties being controlled by their size. Atomic and ionic radii decrease systematically from lanthanum to lutetium as a result of increasing nuclear charge and imperfect shielding of the 4f electrons. Consequently the properties of these species, including their thermodynamic properties and their concentrations in minerals and rocks, vary sympathetically with changes in ionic radii. Only europium shows variable valency in geological environments and may be dominantly divalent or trivalent, depending on the partial pressure of oxygen. The systematic behaviour of the trivalent lanthanides together with the anomalous behaviour of Eu^{2+}, make them a very powerful tool in geochemistry. However, there are few studies that document the concentration of REEs in the suite of minerals composing a rock[6].

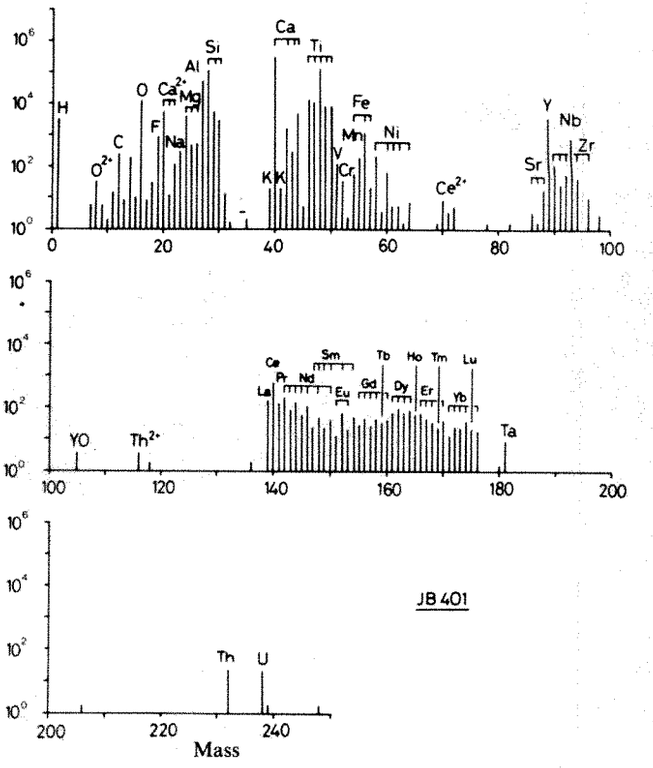

Fig. 1 Secondary ion mass spectrum of a sphene from Cardiff Mine, Ontario, Canada. Count time of 1 s over each integral m/e value.

SIMS has been recognized for some time as the potential 'ultimate weapon' for geochemical analysis[7], however the two major stumbling blocks in realizing this potential have been resolving elemental ions from molecular ions[8], and the inability to quantify secondary ion yields (J.B.M., H.W.N. and G.M.B., in preparation).

There are currently two approaches to removing molecular ion interferences from SIMS spectra. The first involves resolving peaks at the same unit m/e using the small mass difference between elemental and molecular peaks[7–9]. The alternative approach exploits the difference in kinetic energy distribution between molecular and elemental ions to suppress the intensity of the molecular ions. This is possible only with instruments that use a double focusing secondary column geometry such as the Nier design used in the Cameca IMS 3f. Shimizu *et al.*[8,10,11] have refined this technique and shown it to be superior to high mass resolution in a number of applications, particularly at $m/e > 70$.

As discussed recently by Reed[12,13], in the case of the REEs, very high resolution is required to separate the oxide and elemental peaks (for example, a $m/\Delta m > 8{,}000$ is required to separate $^{169}Tm^+$ from $^{153}Eu^{16}O^+$) and the associated intensity loss is prohibitive. Kinetic energy selection fares little better as

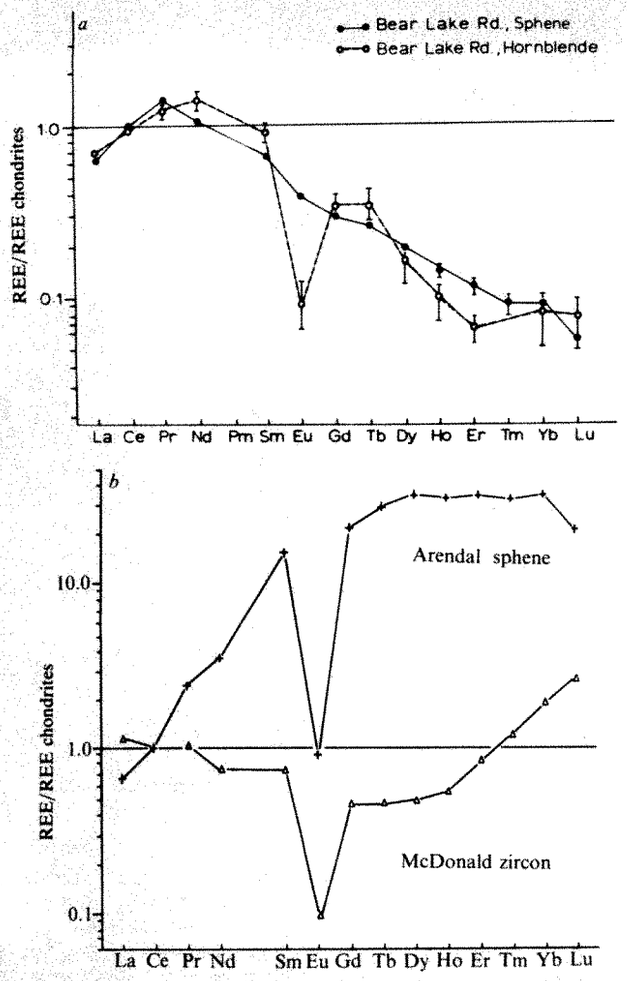

Fig. 2 *a*, Rare earth element distributions from a sphene, hornblende contact from Bear Lake Rd, Ontario, Canada. Intensities are divided by chondritic abundances from ref. 18 and normalized to cerium. In actual abundance $^{140}Ce^+$ sphene/$^{140}Ce^+$ hornblende = 45. Error bars correspond to $\pm 1\sigma$. *b*, Rare earth element distributions from a sphene from Arendal, Norway and a zircon from the McDonald Mine, Ontario, Cadada. Again intensities are compared to chondritic abundances and normalized to cerium.

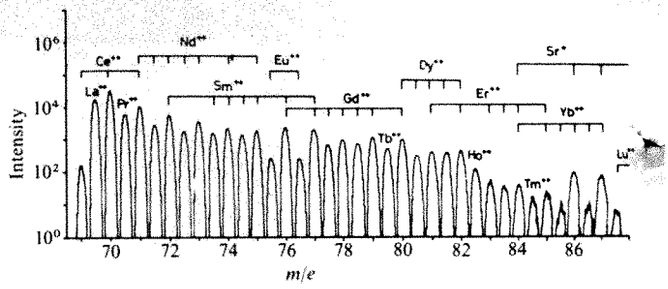

Fig. 3 The complete secondary ion mass spectrum of the monazite sample between $m/e = 69$ and 87, showing the doubly charged ions of the rare earth elements. Total spectrum, 1,000 channels, 5 s per channel.

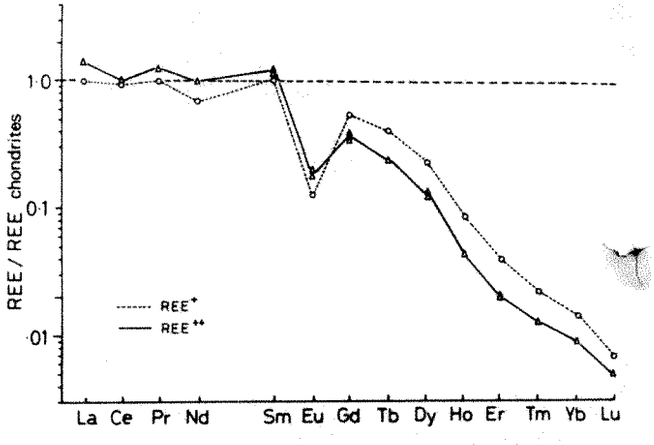

Fig. 4 The distribution of singly and doubly charged ions from the rare earth elements of the New Mexican monazite.

the difference in energy distributions of the REEs and their oxides is not large compared with lighter elements, and the intensity loss with kinetic energy selection is again several orders of magnitude. Clearly, obtaining 'clean' elemental peaks with usable intensities is desirable, and this is the great advantage of the technique described below.

Our results were obtained on a Cameca IMS 3f instrument. A primary beam of $^{16}O^-$ was used exclusively at an accelerating voltage of 11.8–12.2 keV. The specimen isolation technique[1] requires the electrical isolation of the specimen (whether a conductor or insulator) from the sample holder, which in the case of a Cameca IMS 3f carries a secondary accelerating voltage of 4.5 keV. The specimen is thus allowed to charge under the primary beam, creating an extreme kinetic energy selection between the sample surface and the secondary accelerating field. This accounts for the high elemental ion/molecular ion discrimination observed. The lens effect of the sample holder is critical in maintaining usable secondary ion yields in these conditions[1]. The beam conditions necessary to maintain an equilibrium charging rate impose some limitations on spatial resolution. Beam diameters of 40–50 μm in a spot mode, seem to yield optimum secondary ion intensity and stability. In all cases, lens settings in the primary column are determined solely from secondary ion yield and not by reference to the observed primary current. The apertures of the secondary column including the energy slits, remain fully open throughout analysis. This allows a considerable saving in intensity over the standard kinetic energy selection procedure[8].

The six samples used in this study consisted of three sphene ($CaTiSiO_5$) samples, two from Ontario, Canada (Cardiff Mine and Bear Lake Rd) and one from Arendal, Norway, a hornblende in contact with one of the sphenes (from Bear Lake Rd), a zircon crystal from the McDonald Mine, Ontario and a monazite from New Mexico, USA. Count rates for the REEs ranged from 9.5×10^4 c.p.s. from Ce in the monazite to 4×10^2 c.p.s. for Ce in the Cardiff Mine sphene and 36 c.p.s. for Ce in Bear Lake hornblende. The baseline in all cases is <0.1 c.p.s. typical of SIMS measurements.

This study initially concerned the mineral sphene because of its possible use as a host mineral for immobilizing radionuclides from nuclear fuel reprocessing wastes[14,15]. The leaching behaviour of the REEs is considered to be a useful analogue for the behaviour of actinides in such structures. The study of REE distribution and fractionation is also of fundamental geological importance as described above.

Figure 1 shows a complete secondary ion mass spectrum of the Cardiff, Ontario sphene in which the REEs are clearly resolved. To confirm that the rare earth spectra are clear of molecular ions, isotope ratios can be derived for several rare earths (Table 1). The isotope ratios are in very good agreement with literature values[16], particularly for the samples enriched in the heavy REEs (HREEs). There is little interference from hydrides and no measurable contamination of the HREE peaks from oxides of the light REE in the Arendal sphene, although $^{139}La^{16}O^+$ and $^{140}La^{16}O^+$ are probably present in the $^{155,156}Gd^+$ peaks of the Bear Lake sphene.

Despite the multitude of isotopes in the REE mass range and the resulting overlap at many mass units, each element in the

* Peaks at these m/e values consist of an isotope from more than one element.

series has at least one 'clean' isotope. Assuming similar sputtering yields for the REEs, we can equate relative intensity to relative abundance and normalize to chondritic abundance in the usual way. Ion yields are not in fact equal for the REEs as Reed[12,13] has shown. However, a discussion of ion yields in these conditions is beyond the scope of this paper. The resulting rare earth patterns are still a useful fingerprint of the sample and have semiquantitative significance.

The REE patterns (normalized to chondrites) of two sphenes, a hornblende and a zircon are illustrated in Fig. 2. The Bear Lake Rd. sphene and hornblende are of granitic origin and their patterns are similar to sphene and hornblende patterns obtained by others. For example, both the hornblende and zircon patterns are very similar to those observed by Gromet and Silver in hornblende and zircon samples from a Southern Californian granodiorite[6]. This gives the impression that each mineral displays a distinct REE pattern. However, comparison of the Bear Lake and Arendal sphene samples (Fig. 2*a*,*b*) demonstrates unequivocally that the REE patterns of minerals are determined as much by geological settings and processes as they are by mineral chemistry. This result is not surprising in that the geological history of the environment must influence both amounts and fractionation of constituents available to minerals during their formation.

The REE^{2+} spectra give strong confirming evidence that both REE^{+} and REE^{2+} peaks are indeed clean, and should provide important data for understanding ion yields and the fundamental processes of sputtering and ionization. We have observed the complete REE^{2+} spectrum for both the Arendal sphene and the monazite (Fig. 3). Peaks occur at integral and half mass units between $m/e = 69.5$ ($^{139}La^{2+}$) and $m/e = 87.5$ ($^{175}Lu^{2+}$). Isotope ratios of the 2^{+} ions are once again very close to natural abundances (Table 2), and are in very good agreement with the isotope ratios from 1^{+} ions. In both cases, there is some enhancement of the intensity of the lighter isotopes, as is observed for lighter singly charged ions. These data for the doubly charged ions are contrary to the observations of Shimizu and Hart[17], who suggested heavy isotope enrichment for doubly charged ions from pure silver.

The REE^{2+} pattern when normalized to chondritic abundances (Fig. 4), falls below the REE^{+} pattern for the heavier rare earths, in line with the increasing second ionization potentials for the heavier rare earths.

Reed[12] has shown that ion yields for the REE^{+} ions do not simply follow ionization potentials, despite the chemical similarity of these elements. This affects particularly the light REEs La–Eu, and Lu which has both the lowest first ionization potential and the lowest yield. This pattern is clearly visible when comparing REEs with chondritic abundances, where deviations from a smooth curve (apart from Eu anomalies) are noted for La, Ce, Pr and Lu (Figs 2*a*,*b* and 4).

All our results suggest that rapid and reliable REE patterns of minerals can be obtained directly from SIMS results without evaluation of the absolute concentrations of these elements. Reed[12,13] has shown variations in relative ion yields of the REEs but with suitable standards and/or better understanding of ion yields in specimen isolated conditions, quantitative analysis could be achieved. The method is not competitive with neutron activation in sensitivity but for REE levels above 5–10 p.p.m. it offers significant advantages in speed, convenience and perhaps even in accuracy. The absence of background in the mass spectrum combined with improving stability of magnetic analysers mean count times and thus sensitivity can be increased significantly over the values reported here.

We thank Dr N. S. McIntyre for helpful discussion and D. Johnston and W. J. Chauvin of Surface Science Western for experimental assistance. This work was funded in part by Atomic Energy of Canada Ltd in support of the Canadian Nuclear Fuel Waste Management Program.

Evolution of the geomagnetic secular variation field from the beginning of the century

C. Gire, J. L. Le Mouel & J. Ducruix

Institut de Physique du Globe de Paris, Universités de Paris 6 et 7, 4 place Jussieu, 75230 Paris Cedex 05, France

Here we have monitored the secular variation (s.v.) of the geomagnetic field since the beginning of the century using observatory data. The energy of the s.v. field and the westward drift rate decreased from 1912–13 to 1969. Since 1969 these two parameters have again been increasing. The occurrence of jerks (steps in the second time derivative of the field) has been discovered at these two epochs (1912 and 1969). Moreover, after 1969, the s.v. field tends to have the same geographical distribution it had around 1912.

Several years ago it was shown that in 1969 the secular variation (s.v.) $\dot{\mathbf{B}}(P, t)$ of the geomagnetic field $\mathbf{B}(P, t)$ (P is the current point at the Earth's surface, t is time) exhibited a sudden

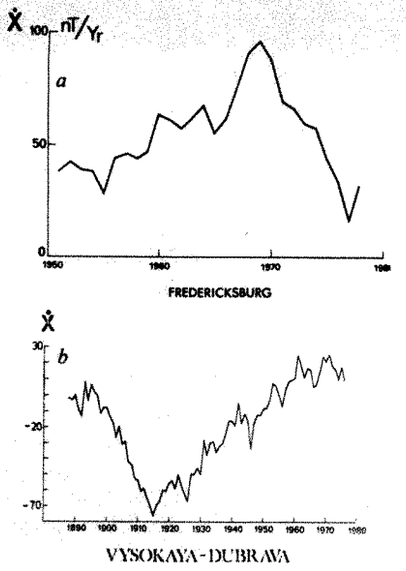

Fig. 1 *a*, The 1969 jerk as seen in the X component at the Fredericksburg observatory. *b*, The 1912 jerk as seen in the X component at the Vysokaya Dubrava observatory. The 1969 jerk at this location is less intense and not as clearly visible as in *a*.

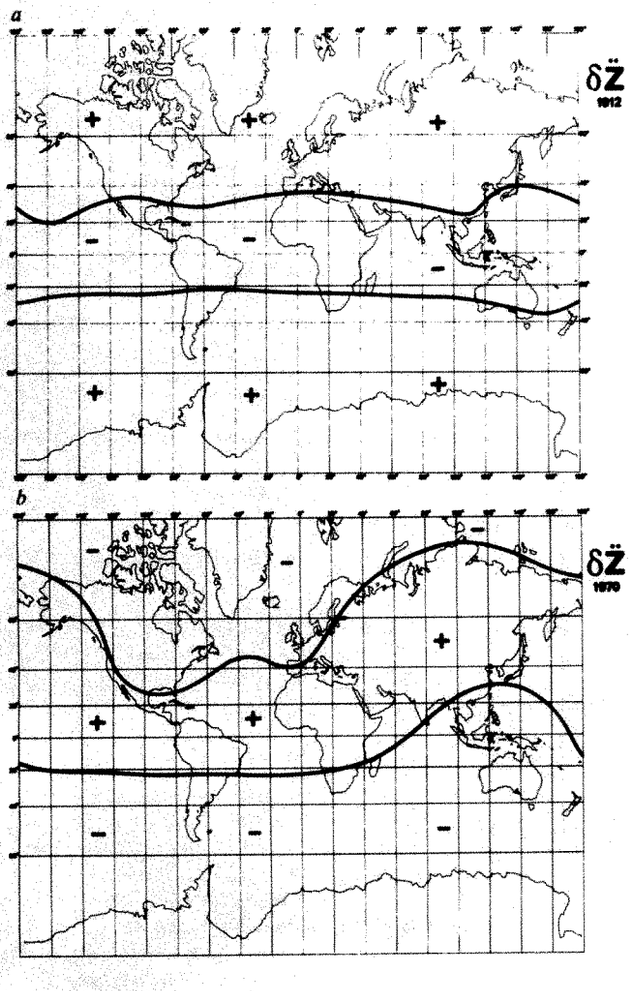

Fig. 2 Comparison between the geographic distributions of the jerks of 1912 and of 1969. The quantity $\delta\ddot{Z}$ is the amplitude of the discontinuity of the second time derivative. Only the zero isopleths are shown.

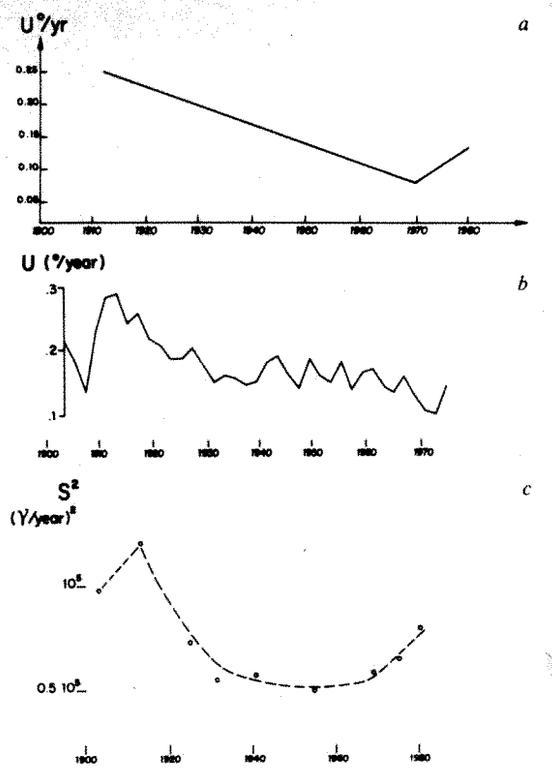

Fig. 3 *a*, Variation with time of the westward drift rate u computed from our simplified model of the geomagnetic secular variation. *b*, Variation with time of the westward drift rate computed using Hodder's method. *c*, Variation with time of the norm of the secular variation as given by spherical harmonic expansions.

change in slope—a step in the second time derivative of the field—of a clearly worldwide character[1–4]. Figure 1*a* illustrates this event, called 'jerk' in English and 'secousse' in French.

More recently Ducruix *et al.*[5] showed that a similar event occurred in 1912–13 (Fig. 1*b*). This event is, of course, less well documented than the 1969 one: only 50 observatories were operating at this time, among which only 10 were in the Southern Hemisphere. Nevertheless, Ducruix *et al.* were able to show that the 1912–13 jerk and the 1969 one have approximately the same geographical distribution, the signs of the second time derivative $\ddot{\mathbf{B}}(P, t)$ jump being reversed. Figure 2 illustrates these geographical distributions.

Ducruix *et al.*, from a close examination of all available secular variation curves, conclude that there is no other similar event over the 1912–80 time interval. Moreover, over this time span, the s.v. field appears to have a rather simple temporal variation: most of the corresponding curves are close to two straight lines, with a discontinuity in slope in 1969. Then, as a first approximation we may write:

$$\begin{aligned} \dot{\mathbf{B}}(P,t) &= \dot{\mathbf{B}}(P,1912) + \vec{\mathbf{b}}(P)\ (t-1912) \qquad 1912 < t < 1969 \\ \dot{\mathbf{B}}(P,t) &= \dot{\mathbf{B}}(P,1969) + \vec{\mathbf{b}}'(P)\ (t-1969) \qquad 1969 < t \end{aligned} \tag{1}$$

In many places, bumps of secular variation, with time constants typically of the order of some tens of years, are superimposed on the schematic s.v. field (1). They tend to obscure the simple broken line pattern which, nevertheless, represents the largest part of the observed s.v. field over the time span considered when studied over the whole Earth's surface.

Let us now choose a single global parameter characteristic of the s.v. field. It is natural to think first of the apparent westward drift (w.d.) rate u. We have computed, from 1912 to 1980, the w.d. rate corresponding to the simplified s.v. field (1) by minimizing quantities such as:

$$\delta^2 = \int \left\{ \left(\dot{\mathbf{B}}(P,t) - u(t) \frac{\partial \vec{\mathbf{B}}}{\partial \phi}(P,t) \right) \right\}^2 \mathrm{d}S \tag{2}$$

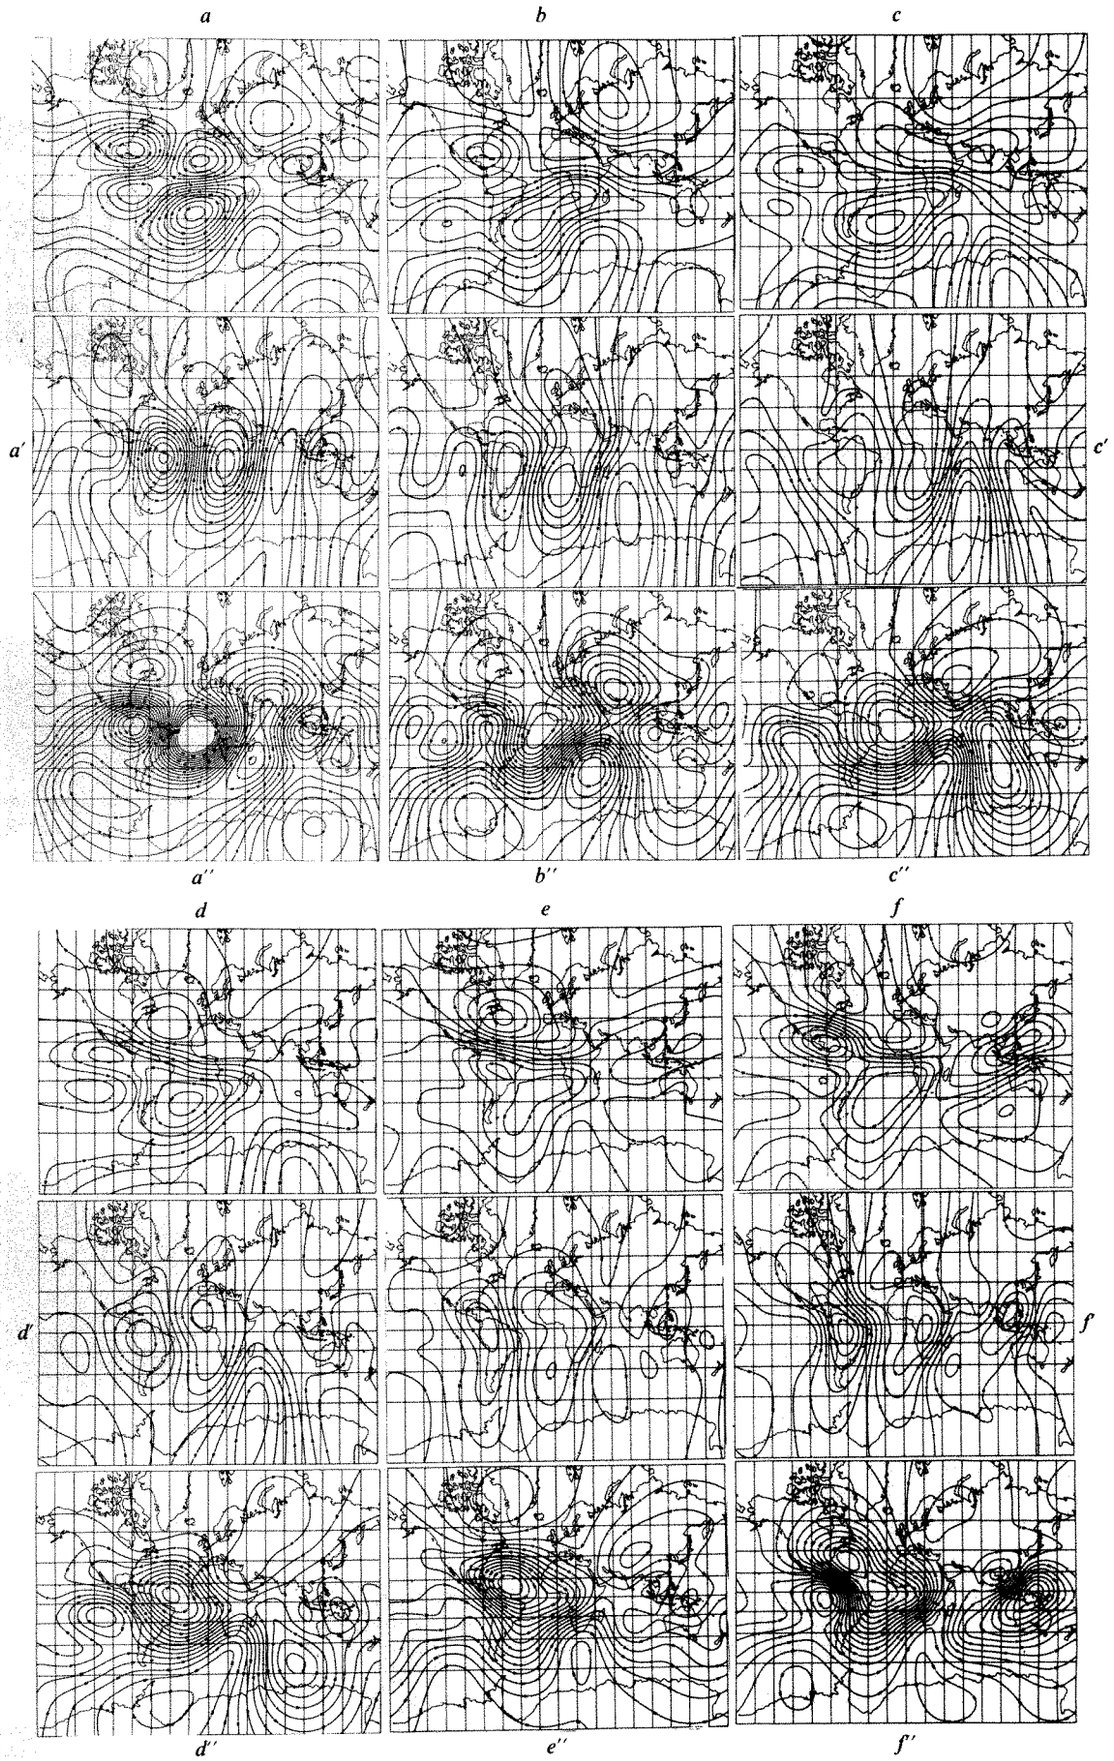

Fig. 4 Evolution with time of the maps of the secular variation for epochs 1913, 1925, 1941, 1955, 1969, 1980 as computed by Hodder. The first row displays the secular variation of X (a–f), the second row s.v. of Y (a'–f'), the third row s.v. of Z (a''–f''). The contour interval is 20 nT $(\text{yr})^{-1}$.

The results are illustrated in Fig. 3*a*. It has previously been shown that the problem of determining u by minimizing quantities such as equation (2) is an ill-posed problem and gives somewhat different values when different techniques and different components of $\vec{\mathbf{B}}$ are used. However, we are only interested here in the trend of the global parameter u from 1912 to 1980—a decrease from 1912 to 1969, then an increase. The 1912–69 decrease also appears in Hodder's estimates[8] derived from raw observatory data (Fig. 3*b*).

Another global parameter is simply the norm $S^2 = \sum_{n,m} (\dot{g}_n^{m^2} + \dot{h}_n^{m^2})(n+1)$ of the s.v. field $\dot{\vec{\mathbf{B}}}$. [$(\dot{g}_n^m, \dot{h}_n^m)$ are the coefficients of the spherical harmonic expansion of $\dot{\vec{\mathbf{B}}}$ with Schmidt's normalization]. Figure 3*c* represents the variation of S^2 with time using s.v. coefficients given by Hodder[9] which rely on observatory data, except in 1980 where the GSFC 1980 s.v. coefficents are used. It appears that the energy decreases steadily from 1912 to 1945, is then nearly constant from 1945 to 1969 (as shown by Fig. 1 of Hodder's paper[9], the lack of homogeneity of the different sets of coefficients can to some extent bias the curve $S^2(t)$, but the general trend can be trusted) and finally increases again after 1969. This confirms the importance and worldwide character of the 1912–13 and 1969 events.

Let us now look at the values of the s.v. field as illustrated by isovalue lines of components $\dot{X}$ (north), $\dot{Y}$ (east) and $\dot{Z}$ (vertical) of $\dot{\vec{\mathbf{B}}}$ for different epochs from 1912 to 1980. The maps in Fig. 4 have been computed, again using s.v. coefficients given by Hodder as above (except for 1980). Despite the uncertainty in the contours of these charts, it is clear that, from the 1912 high of u (or of S^2) to the 1969 low (Fig. 3*a*, *b*), the shape of the s.v. field is evolving monotically; in particular, the isovalue lines get looser and looser, and the s.v. field becomes 'exhausted'. Then the 1969 jerk occurs and the s.v. field increases again and tends to recover the strength it had in 1912. Furthermore, the s.v. field tends to recover, after 1969, the value it had around 1913, at the time of the high of u: the broad lines of maps *a*, *a'*, *a''* and maps *f*, *f'*, *f''* of Fig. 4 indeed present striking similarities (the three components must be considered together) except over the Far-East. Part of the discrepancies could be due to the poor control of 1913 contour lines over these regions.

Unfortunately, these observations are limited to a short time interval. It is, of course, desirable to go back further into the past, but field analysis then relies increasingly heavily on European observatories (19 observatories were operating in 1900, 12 of which were in European countries).

Theoretical studies of the hydrodynamics of the outer core should now account for the occurrence of the 1912–13 and 1969 jerks and for the dramatic change of the secular variation from 1969 to 1980.

Oldest reliable $^{40}Ar/^{39}Ar$ ages for terrestrial rocks: Barberton Mountain komatiites

M. Lopez Martinez*, D. York*, C. M. Hall* & J. A. Hanes†

* Department of Physics, University of Toronto, Toronto, Ontario, Canada M5S 1A7
† Department of Geological Sciences, Queen's University, Kingston, Ontario, Canada K7L 3N6

We report here the first $^{40}Ar/^{39}Ar$ ages for komatiites and komatiitic basalts from the Barberton Mountain Greenstone Belt on the Transvaal–Swaziland border in southern Africa[1]. Both rock types display remarkable argon retentivity. While some variation is found among the samples, the best argon age estimate for the time of metamorphism is in the 3,450–3,490 Myr range. This age is only slightly less than that found in komatiites from the same area by Sm–Nd dating (3,540 ± 15 Myr)[2]. Within the uncertainties of the decay constants involved, the two age estimates are not different. The results show that the principal pervasive greenschist metamorphism[1] in the area must have occurred within 100 Myr of the eruption of the komatiite. Analytically precise ages were obtained despite potassium contents as low as 80 p.p.m. in the presence of high calcium concentrations (3–5% Ca). To our knowledge, the results represent by far the oldest reliable ages obtained for terrestrial rocks using the K–Ar system.

Komatiites have attracted widespread interest among earth scientists[3] because of their unusual geochemistry and mineralogy, and because they are predominantly confined to the Archaean. The Barberton Greenstone Belt contains, in the Onverwacht Group at the base of the Swaziland Supergroup, one of the earliest and best preserved komatiitic sequences. While the time of eruption of these lavas is usually considered to have been established by Sm–Nd dating[2] (Rb–Sr[4] and U–Pb[5] dates were much less precise), the subsequent tectonothermal history has been uncertain. To shed light on the situation, we have carried out a detailed $^{40}Ar/^{39}Ar$ age investigation on ultramafic and mafic lavas from this area.

Table 1 Plateau and integrated ages of komatiite samples

Sample	Integrated age (Myr)	Plateau age (Myr)	% ^{39}Ar release*
Komatiites			
B40A	3,367 ± 8	3,463 ± 7	72
B40A	3,336 ± 4	3,486 ± 3	59
B40A	3,368 ± 15	3,425 ± 17	54
B40A	3,346 ± 11	3,429 ± 10	63
B40A	2,961 ± 14	3,327 ± 9	75
B40A	3,539 ± 55	3,406 ± 37	92
B41B	3,312 ± 25	3,407 ± 17	63
B40E	2,986 ± 6	3,318 ± 7	44
B40E	3,060 ± 5	3,420 ± 6	33
KT7G	2,905 ± 8	3,225 ± 8	29
KT7G	2,962 ± 7	3,298 ± 10	30
KT16A	2,816 ± 3		
KT16A	2,814 ± 2		
Komatiitic basalts			
KT17B	3,778 ± 2	3,428 ± 2	64
KT17B	3,777 ± 2	3,447 ± 2	54
KT17A	3,053 ± 3	3,111 ± 3	53

Decay constants from ref. 14 were used. Errors are $\pm 1\sigma$.
* Per cent of ^{39}Ar release involved in plateau age calculation.

We made 13 step-heating analyses of five different komatiite specimens, and three similar analyses of two different komatiitic basalts, all from the type area[1] of the Komati Formation of the Onverwacht Group. Whole-rock samples, of ~250 mg mass, were irradiated for ~150 h in the McMaster University research reactor. Samples of hornblende 3 gr[6] were irradiated as standards alongside the unknowns and were fused with the Toronto Laser Probe[7] in one-step runs. Irradiated komatiites and komatiitic basalts were step-heated to 1,200 °C using the detailed temperature control vacuum system described by Berger and York[8]. Residues were then fused in a radiofrequency

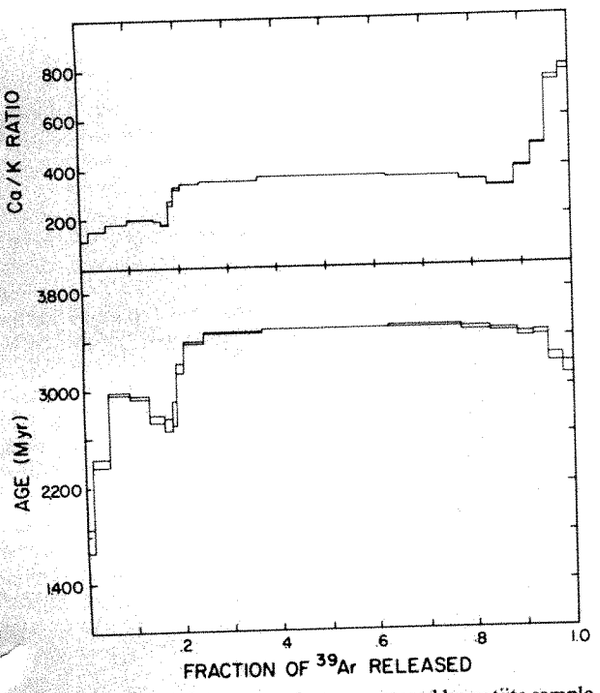

Fig. 1 Age and Ca/K spectra of vacuum-stored komatiite sample B40A. The sizes of the boxes represent 1σ errors, where they are large enough to be shown.

system. Argon isotope ratios in the purified gases were measured with an MS10 mass spectrometer. During the initial analyses it was discovered[9] that the komatiite samples tended to absorb modern atmospheric argon in large quantities after irradiation. A dramatic reduction of this effect was achieved in the later runs by storing the komatiites under vacuum after irradiation until they were required for analysis. These later runs were therefore of higher precision.

The plateau and integrated ages (integrated age = age calculated from the ratio of the total radiogenic ^{40}Ar in the sample to the total potassium-derived ^{39}Ar) are presented in Table 1. Figure 1 shows a typical age spectrum for the komatiites, and the results of duplicate analyses of a komatiitic basalt are shown in Fig. 2. Detailed analytical data will be presented elsewhere.

From Table 1 it can be seen that the komatiites have lost some argon, as the integrated ages are (with one exception out of 13) significantly less than the Sm–Nd age of 3,540 ± 15 Myr. Despite this, plateau ages approaching 3,500 Myr are obtained by the step-heating approach.

The first sample examined, B40A, has been studied in the greatest detail. The fifth and sixth runs on this sample in Table 1 were our earliest[9] and are not of as high a quality as the top four runs listed, which were performed after techniques appropriate to komatiites had been devised. These four superior analyses all yielded integrated ages between 3,300 and 3,400 Myr. It is interesting that two of these four samples, having been vacuum-stored after irradiation, suffered accordingly much lower modern atmospheric argon contamination and yielded the highest plateau ages: 3,463 ± 7 and 3,486 ± 3 Myr. The latter age corresponds to the plateau in the age spectrum illustrated in Fig. 1. In this analysis we extracted gas in several small steps at both ends of the obvious age plateau in order to minimize mixing of adjacent off-plateau gas of low age with the true plateau. Therefore, it may be significant that this extremely precise plateau age (the error in the plateau age = 3 Myr (1σ)) is also the oldest we have yet found.

The shape of the age spectrum in Fig. 1 is characteristic of all those found in the komatiite specimens, except for KT16A, which will be referred to below. This characteristic age spectrum contains three totally distinct portions, with three correspondingly distinct segments in the Ca–K spectrum (shown in the top part of Fig. 1). The low temperature release (600–800 °C)

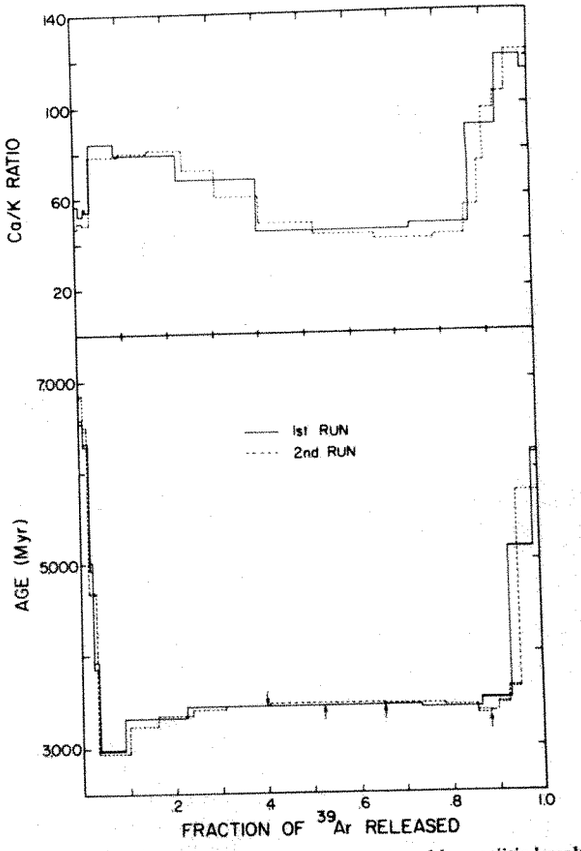

Fig. 2 Age and Ca/K spectra of vacuum-stored komatiitic basalt sample KT17B. Where they are large enough to be shown, the 1σ errors are represented by the sizes of the boxes. Arrows indicate divisions between two fractions of equal age. Note that the Ca/K values and the shape of the Ca/K spectrum are very different from those found in the komatiite samples (see Fig. 1).

displays relatively low ages and Ca/K ratios of ~200. At intermediate temperatures (925–1,035 °C) the typical age plateau appears, together with a new Ca/K regime having a value in the range 350–500 depending on the sample. At the highest temperatures (≥1,100 °C) there is a slight but experimentally reproducible dip in the age along with a large increase in Ca/K ratios. Petrographically, the komatiites retain some primary textures, but consist almost entirely of metamorphic assemblages: serpentine–tremolite–chlorite–magnetite and very minor ferristilpnomelane. Electron microprobe X-ray scans and quantitative analyses show that the only mineral present in sufficient quantity in the komatiite, with the required Ca/K ratio to account for the plateau segment in the age spectrum, is tremolite. The younger ages in the low temperature release range are correlated with the presence of stilpnomelane.

Komatiite specimen B41B also has an integrated age of over 3,300 Myr and displays a plateau age of 3,407 ± 17 Myr, the slightly larger error here being due to the fact that this sample has the lowest potassium content (80 p.p.m.) of all the komatiites examined.

The remaining three komatiites (B40E, KT7G and KT16A) all exhibit greater argon losses from their whole-rock systems, having integrated ages in the 3,060–2,814 Myr range. The lowest such value (2,814 Myr) was obtained for KT16A which, presumably because of its severe disturbance, also displays no plateau in its age spectrum. In contrast, samples B40E and KT7G do show age plateaus, in the 3,420–3,225 Myr range, despite large total argon losses.

The two komatiitic basalts analysed behave completely differently from the komatiite samples and from each other. KT17A shows severe argon loss (integrated age = 3,053 ± 3 Myr) and a ragged age spectrum with a crude plateau at 3,100 Myr. In complete contrast with this, and with all the komatiites so far

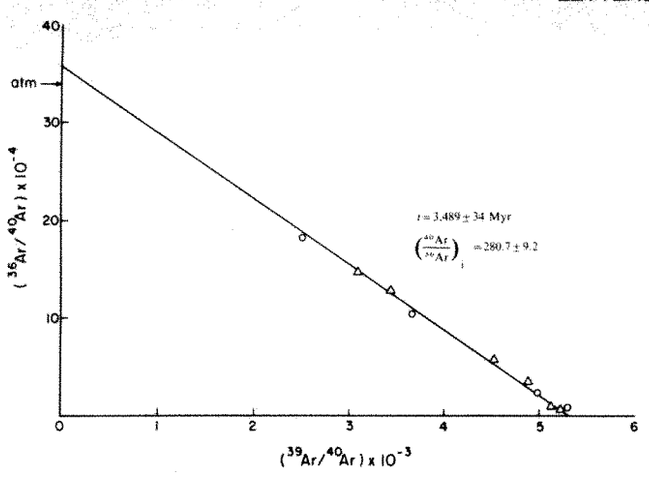

Fig. 3 Isotope correlation plot for the data from the plateaux of the high-precision vacuum-stored analyses of B40A. Except for two points where the errors are approximately the same size as the symbols, the errors in the data are less than the dimensions of the symbols. ○, First run; △, second run.

analysed, komatiitic basalt KT17B contains excess radiogenic argon. Thus, duplicate step-heating analyses gave integrated ages of 3,777 ± 2 and 3,778 ± 2 Myr, ~240 Myr older than the Sm–Nd age. However, as may be seen in Fig. 2, the step-heating experiments are remarkably successful in removing the effect of the excess argon. The well known saddle-shaped spectrum frequently found in samples containing excess argon[10] is observed. A very broad well-defined plateau is revealed in the middle temperature (900–975 °C) fractions, yielding plateau ages of 3,428 ± 2 and 3,447 ± 2 Myr for the duplicates. The latter value was obtained in an experiment in which we took extra, small steps at both ends of the age plateau to reduce the effect of mixing off-plateau gas with the plateau fractions. As with B40A (referred to above) this did seem to produce a slightly higher plateau age.

The komatiitic basalts are comprised of actinolite with rims and patchy intergrowths, crystallographically controlled, of ferro-hornblende, epidote-choked albite, chlorite and altered titanomagnetite with associated minor ferristilpnomelane. Electron microprobe analyses, coupled with the Ca/K spectra from the age runs, show that the age plateaux are dominated by argon release from hornblende, while disturbed portions of the spectra appear related to stilpnomelane. As far as we know, this is the first report of stilpnomelane in either Barberton komatiites or komatiitic basalts, and indicates a condition of low oxygen fugacity during the main metamorphism, with the stilpnomelane having originally formed as ferrostilpnomelane[11]. The later oxidation to ferristilpnomelane may be reflected in the younger ages in the low temperature release range of the komatiites.

With the exception of komatiite sample KT16A which retained some primary olivine, all the samples consist of metamorphic mineral assemblages. We conclude, therefore, that the tremolite in the komatiites and the hornblende in the komatiitic basalt (KT17B) both record the time of the metamorphism of the Komati Formation. From the superior analyses of B40A and KT17B we place this metamorphism somewhere in the 3,450–3,490 Myr age range (within experimental errors). Evidently this principal, pervasive metamorphism[1] occurred within less than 100 Myr of eruption (possibly almost immediately after, when uncertainties in the ^{40}K and ^{147}Sm half lives are considered) of the komatiites. Chauvel *et al.*[12] have recently suggested that in certain circumstances Sm–Nd dates on komatiitic rocks may be anomalously old. Our data indicate that this is not the case here.

All our measurements were corrected for instrumental argon blanks. Any ^{36}Ar remaining after that was used to make a modern atmospheric argon correction. *A priori*, it was, of course, not obvious to us that this would be the correct procedure. Conceivably, the samples may have contained initial argon having a $^{40}Ar/^{36}Ar$ ratio totally different from that found in today's atmosphere. That no significant error has been introduced, however, is apparent from the consistency of the data in the presence of a wide range of ^{36}Ar-based corrections. To test this point further and indeed to look for primordial argon, we examined the distribution of the data from the plateaux of the high-precision vacuum-stored B40A runs (the top two analyses in Table 1) on a graph of $^{36}Ar/^{40}Ar$ versus $^{39}Ar/^{40}Ar$ (Fig. 3). The best straight line[13] allowing for all reasonable sources of correlation in the errors, gives an age of 3,489 ± 34 Myr. While the data are highly linearly correlated, they are more scattered about the best line than would be expected on the basis of experimental error alone. The intercept on the $^{36}Ar/^{40}Ar$ axis indicates initial argon in the samples with a $^{40}Ar/^{36}Ar$ ratio of 280.7 ± 9.2 (1σ, where the error allows for the scatter of the samples about the line). While this is lower than the modern atmospheric value of 295.5, the difference is not statistically significant. Only more detailed studies will show whether this intercept indicates some sort of primordial argon or whether it represents a mixture of initial argon heavily contaminated with modern atmospheric argon, despite our attempt to eliminate this by post-irradiation vacuum storage. Until such measurements have been performed, the data do not allow us to favour any particular one of the theories of mantle–atmosphere evolution.

Finally, as mafic and ultramafic rocks (both komatiitic and tholeiitic) constitute volumetrically the bulk of Archaean greenstone belts, our demonstration here of the precise dating of the greenschist metamorphism of individual komatiitic lavas indicates the potential value of the $^{40}Ar/^{39}Ar$ dating method in elucidating the tectonothermal history of these terrains.

We thank Maarten J. de Wit and Chris J. Hale for supplying the samples, and W. John Kenyon and Peter Kuybida for technical assistance. This research was funded by grants to D.Y. and J.A.H. from the Natural Science and Engineering Research Council of Canada, and by a grant to J.A.H. from the Queen's University Advisory Research Committee. M.L.M. was supported by the Consejo Nacional de Ciencia y Tecnologia (Mexico).

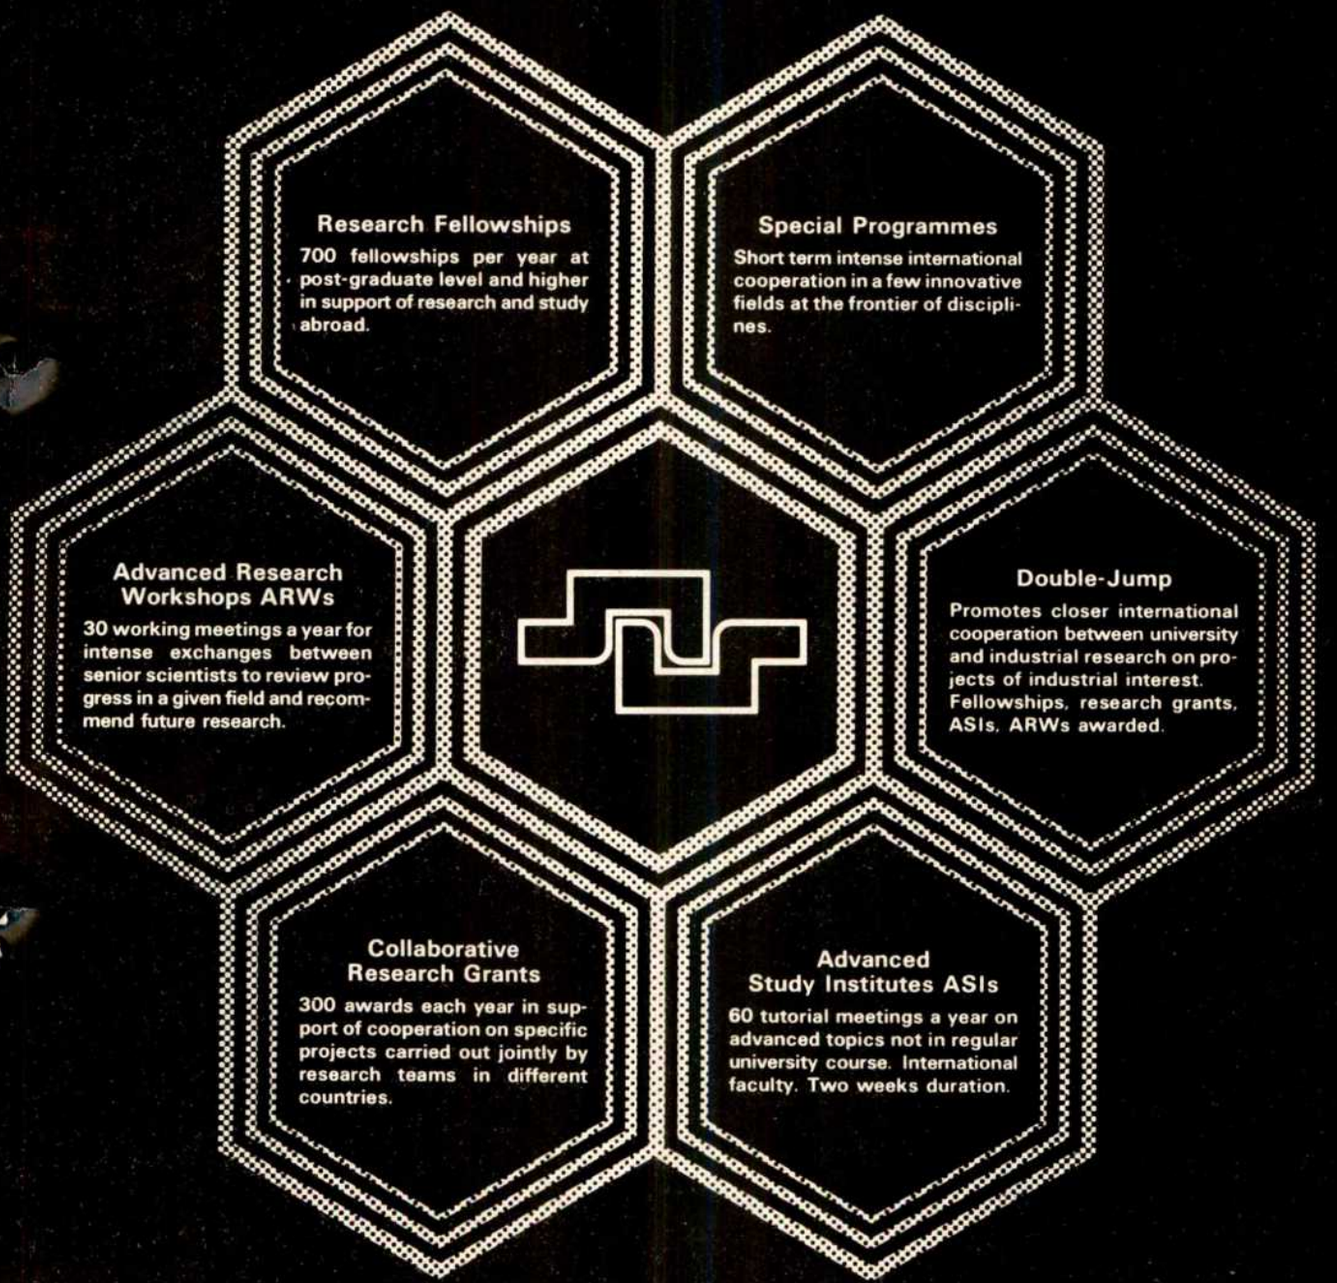
Dating diagenesis in a petroleum basin, a new fluid inclusion method

R. S. Haszeldine, I. M. Samson* & C. Cornford

Britoil PLC Stratigraphic Laboratory, 150 St Vincent Street, Glasgow G2 5LJ, UK
* Department of Applied Geology, University of Strathclyde, Glasgow, G1 1XJ, UK



The final porosity and permeability of sandstone petroleum reservoirs is greatly affected by the diagenetic growth of minerals after deposition. For example a sand may be deposited with a porosity of 25% and a permeability of 5,000 mdarcy (mD)[1]; diagenetic growth of quartz around detrital sand grains may leave a rock with only 10% porosity, and later growth of

NATO Advanced Study Institutes

Cours d'été

ADVANCED STUDY INSTITUTES (ASIs) are tutorial courses of two weeks' duration on new, important topics for up to 1 scientists and research students. They aim at the dissemination of advanced scientific knowledge and promotion of internatio contacts among scientists. No tuition fees are requested from participants; some may obtain small grants through the meeti Director to assist with travel and living expenses.

Each meeting is held under the responsibility of its Director, to whom all requests for information, attendance or support should addressed. The meetings marked ● are of particular industrial interest. One meeting is a Training Course sponsored under the Spec Programme on Marine Sciences (MS). **Locations and dates may change.** Titles and addresses have been abridged. Many meetings are an interdisciplinary nature : please check all subject areas.

PUBLICATIONS :
Proceedings of meetings are published in the NATO ASI Series by : **Plenum - Reidel - Nijhoff - Springer Verlag.**

LIFE SCIENCES

MOLECULAR FORM & FUNCTION OF THE PLANT GENOME
Dr. L. VAN VLOTEN-DOTING, Dept. of Biochemistry, P.O. Box 9505, 2300 RA Leiden, The Netherlands
4-14 July 1984 : Renesse, The Netherlands 438/83

CELLULAR & MOLECULAR ASPECTS OF DEVELOPMENTAL BIOLOGY
Mr. R. STORA, Division Théorique, CERN, CH-1211 Geneva 23, Switzerland
1-27 July 1984 : Les Houches, France 444/83

NEW DEVELOPMENTS & METHODS IN MEMBRANE RESEARCH & BIOLOGICAL ENERGY TRANSDUCTION
Prof. L. PACKER, Membrane Bioenerg. Gp., Dept. Physiology/Anatomy, Univ. California, Berkeley, CA 94720, USA
16-29 August 1984 : Spetsai, Greece 449/83

GENOME ORGANIZATION & FUNCTION
Prof. H.G. ZACHAU, Inst. F. Physiol. Chem., Goethestr. 33, D-8000 München 2, Germany
30 August-12 September 1984 : Spetsai, Greece 693/83

CELL TRANSFORMATION
Dr. J.E. CELIS, Inst. of Chemist., University, Langelandsgade 140, DK-8000 Aarhus, Denmark
2-12 September 1984 : Alcabideche, Portugal 760/83

TOXICOLOGY OF THE NERVOUS SYSTEM
Prof. C.L. GALLI, Inst. Pharmacology & Pharmacognosy, Univ., Via Balzaretti 9, 20133 Milan, Italy
10-21 September 1984 : Maratea, Italy 794/83

RADIATION CARCINOGENESIS AND DNA ALTERATIONS
Prof. F.J. BURNS, Dept. Environ. Medicine, NY Univ. Medical Ctr., 550 First Ave., New York, NY 10016, USA
30 September-13 October 1984 : Greece 795/83

CELLULAR AND MOLECULAR CONTROL OF DIRECT CELL INTERACTIONS IN DEVELOPING SYSTEMS
Dr. H.J. MARTHY, Lab. Arago (LA 117 CNRS), F-66 650 Banyuls-sur-Mer, France
10-23 September 1984 : Banyuls-sur-Mer, France 831/83

DRUGS AFFECTING LEUKOTRIENES AND OTHER EICOSANOID PATHWAYS
Prof. F. BERTI, Dept. Pharmacology, Univ., Via Balzaretti 9, 20129 Milan, Italy

26 March - 6 April 1984 : Newcastle-upon-Tyne, UK 1013/83

AIR-SEA TRANFER PROCESSES - TRAINING COURSE (MS)
Dr. K. KATSAROS, Dept. Atmosph. Science AK-40, Univ. Washington, Seattle, Washington 98195, USA
Date to be announced : Lake Washington, USA 1016/83

MATHEMATICS

COMPUTATIONAL MATHEMATICAL PROGRAMMING
Prof. K. SCHITTKOWSKI, Inst. fuer Informatik, Univ. Stuttgart, Azenbergstr. 12, 7000 Stuttgart 1, Germany
23 July - 2 August 1984 : Bad Windsheim, Germany 478/83

OPERATORS AND FUNCTION THEORY
Dr. S.C. POWER, Dept. Mathematics, Univ. Lancaster, Bailrigg Lancaster, LA1 4YL, UK
15 - 26 July 1984 : Lancaster, UK 518/83

RINGS AND GEOMETRY
Prof. R. KAYA, Anadolu Universitesi Fen-Ed., Fakultesi, Ogretim Uyesi, Eskisehir, Turkey
2 - 14 September 1984 : Istanbul, Turkey 696/83

UNIVERSAL ALGEBRA AND RELATIONS
Prof. P. BERTHIAUME, Sémin. Math. Sup., Univ., C.P. 6128, Succ. A, Montreal, Que., Canada H3C 3J7
16 July - 3 August 1984 : Montreal, Canada 697/83

GRAPHS AND ORDERS
Dr. I. RIVAL, Dept. Math. & Stat., Univ., 2500 University Drive N.W., Calgary, Alberta T2N 1N4, Canada
20 May - 1 June 1984 : Banff, Canada 969/83

INFORMATICS

CONTROL FLOW & DATA FLOW – CONCEPTS OF DISTRIBUTED PROGRAMMING ●
Prof. F.L. BAUER, Inst. Inform., Techn. Univ., Arcisstr. 21, Postfach 20 2420, D-8000 München 2, Germany
31 July - 12 August 1984 : Marktoberdorf (Nr Munich) Germany 685/83

NEW SYSTEMS & ARCHITECTURES FOR AUTOMATIC SPEECH RECOGNITION & SYNTHESIS ●
Prof. R. DE MORI, Comp. Sc., 1455 De Maisoneuve Blvd West, Rm H961-22, Montreal, Quebec, Canada H3G 1M8
2 - 14 July 1984 : Bonas, France 712/83

RELATIONAL DATA BASE SYSTEMS DESIGN AND IMPLEMENTATION ●
Dr. C.J. ROGERS, Software & Inform. Syst. Div., TRW Def. Syst. Gp., 1145 Arques Av., Sunnyvale, CA 94086, USA
17 June - 29 July 1984 : Bad Windsheim, Germany 992/83

LOGICS FOR VERIFICATION AND SPECIFICATION OF PROGRAMS ●
Dr. K.R. APT, L.I.T.P., Univ. de Paris VII, 2 Place Jussieu, F-75251 Paris, France
15 - 19 October 1984 : France 995/83

APPLIED SCIENCES & ENGINEERING

GLASS CURRENT ISSUES ●
Dr. J. DUPUY, Dép. Physique des Matériaux, 43 Bd. du 11 Nov.1918, 69622 Villeurbanne, Cedex, France
2 - 13 April 1984 : Tenerife, Spain 10/83

INDUSTRIAL ROBOTIC VISION ●
Dr. A. OOSTERLINCK, Centrum Menselijke Erfelijkheid, Minderbroedersstraat 12, B-3000, Leuven
6 - 17 August 1984 : Leuven, Belgium 135/83

PHYSICS & ENGINEERING OF MEDICAL IMAGING ●
Dr. R. GUZZARDI, Nuclear Measurements Unit, C.N.R., Inst. Clin. Phys., Via Savi, 8, I-56100 Pisa, Italy
23 September - 5 October 1984 : Maratea, Italy 139/83

THERMODYNAMICS & FLUID MECHANICS OF TURBOMACHINERY ●
Prof. A.S. ÜCER, Mechanical Engineering Dept., Middle East Techn. Univ., Ankara, Turkey
17 - 28 September 1984 : Izmir-Cesme, Turkey 435/83

ADAPTIVE METHODS IN UNDERWATER ACOUSTICS ●
Ing. H. URBAN, Fried. Krupp GmbH, Krupp Atlas-Elektronik, PO. Box 44 85 45, D-2800 Bremen 44, Germany
30 July - 10 August 1984 : Lüneburg, Germany 439/83

ADVANCED AGRICULTURAL INSTRUMENTATION ●
Dr. W.G. GENSLER, Dept. of Electrical Engineering, Univ. Arizona, Tucson, AZ 85721, USA
27 May - 9 June 1984 : Italy 736/83

MINERAL PROCESSING DESIGN ●
Prof. Z.M. DOGAN, Mining Engineering Department, Middle East Technical Univ., (METU) Ankara, Turkey
6 - 17 August 1984 : Ankara, Turkey 772/83

OPTICAL METROLOGY ●
Dr. O.D.D. SOARES, Lab. de Fisica, Faculdade de Ciencias, 4000 Porto, Portugal
6 - 17 August 1984 : Povoa de Varzin, Portugal 945/83

MICROARCHITECTURE OF VLSI COMPUTERS ●
Dr. P. ANTOGNETTI, Istituto di Eletrotechnica, Univ. of Genova, Viale Cause 13, 16145 Genova, Italy
July 1984 : Urbino, Italy 970/83

APPLICATIONS OF THE MATERIAL SCIENCES TO THE PRACTICE OF ORTHOPEDIC SURGERY ●
Dr. M. DUJOVNY, Dept. Neurological Surgery, Henry Ford Hospital, 2799 W. Grand Blvd, Detroit, MI 48202, USA
15 - 28 July 1984 : Marbellia, Spain 972/83

rther information on a particular meeting should be obtained from the meeting Director named above.

rther information on the NATO Science Programmes may be obtained from : NATO Scientific Affairs Division, B-1110 Brussels, Belgium.

NATO Advanced Research Workshops

Tables rondes de l'OTAN

ADVANCED RESEARCH WORKSHOPS (ARWs) are working meetings which enable leading researchers, scientists and engineers to review the state-of-the-art in specific topics in fast moving fields and to formulate recommendations for the future. They are of about five days' duration : **attendance is limited and usually by invitation only.**

Each meeting is held under the responsibility of its Director, to whom all requests for information, attendance or support should be addressed. Four of the meetings are being sponsored by the Special Programmes on Global Transport Mechanisms (GTM), Selective Activation of Molecules (SAM), Materials Science (Mat.S) and the Survey Group on Astronomy (Astron.). The meetings marked ● are of particular industrial interest. **Locations and dates may change.** Titles and addresses have been abridged. Many meetings are of an interdisciplinary nature : please check all subject areas.

PUBLICATIONS :
Proceedings of meetings are published in the NATO ASI Series by : **Plenum – Reidel – Nijhoff – Springer Verlag.**

LIFE SCIENCES

MECHANISMS OF PERCEPTION & ORIENTATION TO INSECT PHEROMONES
Dr. M.C. BIRCH, Dept. of Zoology, South Parks Road, Oxford OX1 3PS, UK
5-10 August 1984 : Oxford, UK 75/82

MODELLING THE GROWTH OF WHEAT
Dr. W. DAY, Dept. of Agricult. & Horticult., Univ. Bristol, Long Ashton Research Station, Bristol BS18 9AF, UK
9-12 April 1984 : Bristol, UK 437/83

FUNCTION, STRUCTURE & GENETICS OF PROKARYOTIC & EUKARYOTIC ELONGATION FACTORS
Dr. A. PARMEGGIANI, Laboratoire de Biochimie, Ecole Polytechnique, F-91128 Palaiseau Cedex, France
16-20 July 1984 : Thiverval-Grignon, France 743/83

THE PHYSIOLOGY OF THIRST AND SODIUM APPETITE
Dr. G. DE CARO, Inst. of Pharmacology, Univ. of Camerino, 62032 Camerino, Italy
11-21 July 1984 : Camerino, Italy 767/83

VISUAL SPATIAL PROSTHESES FOR THE BLIND ●
Prof. D.H. WARREN, College Humanities & Social Sciences, Univ. of California, Riverside, CA 92521, USA
30 April-3 May 1984 : San Bernardino, USA 710/83

HUMAN IN VITRO FERTILIZATION - PRESENT PROBLEMS AND PROSPECTS
Prof. J. TESTART, Inserm 187, Gynéc.-Obstét., Antoine-Béclère, 157 rue Pte-de-Trivaux, 92141 Clamart, France
19-22 September 1984 : Cargèse, Corsica, France 757/83

MECHANISMS OF SECONDARY BRAIN DAMAGE
Prof. A. BAETHMANN, Inst. Surgical Research, Univ., Klinikum Grosshardern, 7000 München 70, Germany
19-23 February 1984 : Mauls/Sterzing, Italy 774/83

MULTIDISCIPLINARY ANALYSIS OF EVOLUTIONARY RELATIONSHIPS AMONG RODENTS
Dr. W.P. LUCKETT, Dep. Anatomy, Univ., Medical Sciences, G.P.O. Box 5067, San Juan, Puerto Rico 00936, USA
2-6 July 1984 : Paris, France 788/83

SYMPOSIUM ON BIOLOGY OF INVERTEBRATE AND LOWER VERTEBRATE COLLAGENS
Dr. S. BAIRATI, Dept. General Physiology & Biochemistry, Univ. of Milano, Via Celoria 26, 20133 Milano, Italy
3-6 June 1984 : Como, Italy 956/83

THE IN VITRO EFFECTS OF MINERAL DUSTS
Prof. E.G. BECK, Inst. of Hygiene, Justus-Liebig Univ., 63 Giessen, Germany
11-14 September 1984 : Schluchsee-Hochschwarzwald, Germany 976/83

STANDARDIZATION OF METHODOLOGY FOR THE MYCOLOGICAL EXAMINATION OF FOODS
Dr. J.E.L. CORRY, Min. of Agriculture Fisheries & Food, (Food Sc. Div.), 65 Romney Str., London SW1P 3RD, UK
July 1984 : Boston, USA 980/83

COORDINATE REGULATION OF CHOLESTEROL METABOLISM IN THE LIVER
Dr. A. SANGHVI, Dep. of Pathology, Univ. of Pittsburgh, School of Medicine, Pittsburgh, PA 16261, USA
October 1984 : Santa Fe, New Mexico, USA 990/83

ECOLOGY

ENVIRONMENTAL MONITORING FOR ARCHITECTURAL CONSERVATION
Dr. R.A. LIVINGSTON, RD-677, Res. & Dev., EPA, 401 M St SW, Washington, DC 20460, USA
11-15 June 1984 : Rome, Italy 459/83

POPULATION BIOLOGY - THE INTERFACES
Dr. P. JACQUARD, Dep. Physiologie Ecologique, C.N.R.S., B.P. 5051, 34033 Montpellier, France
28 May-2 June 1984 : Montpellier, France 876/83

SOCIAL, BEHAVIOURAL & POLITICAL SCIENCES

RESEARCH IN USER-COMPUTER INTERACTION ●
Prof. B. SCHACKEL Dept. of Human Sciences, University of Technology, Loughborough, UK
9-14 September 1984 : Cambridge or Loughborough, UK 968/83

PHYSICS

CONDENSED MATTER RESEARCH USING NEUTRONS, TODAY & TOMORROW
Dr. S.W. LOVESEY, Rutherford Appleton Lab., Chilton, Oxfordshire, OX11 0QX, UK
26-29 March 1984 : Abingdon, Nr. Oxford, UK 479/83

CHEMISTRY, GEOPHYSICS AND ASTROPHYSICS

THE MORPHOLOGY & DYNAMICS OF THE POLAR CUSP
Prof. A. EGELAND, Inst. of Physics, Univ. Oslo, P.O. Box 1048, Blindern, N-Oslo 3, Norway
20-27 May 1984 : Lillehammer, Norway 434/83

COMPOSITION & INTERACTIONS OF SOIL COLLOID SURFACES
Prof. M.F.L. DE BOODT, Fakult. Landbouw, RUG, Coupure Links 533, B-9000 Gent
2-8 September 1984 : Gent, Belgium 515/83

MOLECULAR ASTROPHYSICS – STATE OF THE ART & FUTURE DIRECTIVES
Dr. G.H.F. DIERCKSEN, Inst. Astrophysik, Karl-Schwarzschild-Str. 1, D-8046 Garching bei München, Germany
8-14 July 1984 : Bad Windsheim, Germany 741/83

EVOLUTION OF STRUCTURE IN THE UNIVERSE
Prof. M.J. REES, Inst. of Astronomy, Madingley Road, Cambridge CB3 0HA, UK
January 1984 : Santa Barbara, California, USA 768/83

CHAOS IN ASTROPHYSICS
Prof. J.R. BUCHLER, Dept. of Physics, Univ. of Florida, Gainsville, FL. 32611, USA
8-11 April 1984 : Palm Coast, Florida, USA 797/83

PHASE TRANSITIONS IN THE VERY EARLY UNIVERSE
Prof. R. BAIER, Fakultät für Physik, Univ. Bielefeld, Postfach 8640, D-4800 Bielefeld 1, Germany
4-8 June 1984 : Bielefeld, Germany 859/83

TRANSPORT IN NON-STOICHIOMETRIC COMPOUNDS ●
Prof. G. SIMKOVICH, Dept. Mat. Sc. & Eng., 206 Steidle Bldg, Penn. State, University Park, PA 16802, USA
10-16 June 1984 : University Park, Pennsylvania, USA 861/83

POLYDIACETYLENES - SYNTHESIS, STRUCTURE AND ELECTRONIC PROPERTIES ●
Dr. R.R. CHANCE, Corporate Technology, Allied Corporation, P.O. Box 1021R, Morristown, NJ 07960, USA
12-17 August 1984 : Stratford-upon-Avon, UK 959/83

COMPUTER SIMULATION OF CONDENSED MATTER (Mat.S)
Dr. C.R.A. CATLOW, Dep. Chemistry, Univ. College London, 20 Gordon Street, London WC1H 0AJ, UK
22-27 July 1984 : Norwich, UK 758/83

ICE IN THE SOLAR SYSTEM (Astron.)
Prof. A. DOLLFUS, Observatoire de Paris, 92190 Meudon, France
16-19 January 1984 : Nice, France 450/83

BIOGEOCHEMICAL CYCLING OF S & N IN REMOTE AREAS (GTM)
Dr. J.N. GALLOWAY, Environmental Studies Dept., Univ. Virginia, Charlottesville, VA 22903, USA
8-12 October 1984 : St. Georges, Bermuda 771/83

THE CHEMISTRY OF WEATHERING (GTM)
Dr. J.I. DREVER, Geology Dep., Univ. of Wyoming, Laramie, WY 82071, USA
25-29 June 1984 : Bonas, France 977/83

LASER STUDIES IN REACTIONS KINETICS VIA THE SELECT. ACTIVAT. OF MOLECULES (SAM) ●
Prof. E.W. SCHLAG, Inst. F. Physik. und Theoret. Chemie, Lichtenbergstrasse 4, 8046 Garching, Germany
24-27 September 1984 : Bavaria, Germany 1000/83

SELECTIVE ACTIVATION OF ORGANIC COMPOUNDS - ELECTROSYNTHESIS (SAM) ●
Dr. J.H.P. UTLEY, Dept. Organic Chem., Queen Mary Coll., Univ. of London, Mile End Road, London E1 4NS, UK
9-13 September 1984 : Oxford, UK 1011/83

UTILIZ. OF ACTIVATED DIOXYGEN SPECIES IN THE SELECT. OXIDAT. OF SUBSTRATES (SAM) ●
Prof. G. MODENA, Ist. di Chimica Organica dell'Universita, via Marzolo, 1, 35131 Padova, Italy
25-29 June 1984 : Galzignano (Padua), Italy 770/83

ASYMMETRIC CATALYSIS (SAM)
Prof. B. BOSNICH, Dept. of Chemistry, Univ. Toronto, 80 St. Georges St., Toronto M5S 1A1, Canada
2-7 January 1984 : Florida, USA 756/83

MATHEMATICS

DIFFERENTIAL GEOMETRY IN STATISTICAL INFERENCE
Prof. D.R. COX, Dept. Mathematics, Imperial College, Huxley Building, 180 Queen's Gate, London SW 7 2BZ, UK
9-11 April 1984 : London, UK 701/83

COMBINATORIAL ALGORITHMS ON WORDS
Ing. A. APOSTOLICO, Ist. di Scienza dell'Inform., Fac. di Scienze, Univ. di Salerno, I-84100 Salerno, Italy
18-22 June 1984 : Salerno, Italy 804/83

INFORMATICS

FORMAL SOFTWARE DEVELOPMENT METHODS ●
Prof. D. BJORNER, Dansk Datamatik Center, Lundtoftevej 1 C, DK-2800 Lyngby, Denmark
21-25 May 1984 : Denmark 979/83

APPLIED SCIENCES & ENGINEERING

PARTIAL PRESTRESSING – FROM THEORY TO PRACTICE ●
Prof. M.Z. COHN, Dept. Civil Engineering, Univ. Waterloo, Waterloo, Ontario, N2L 3G1, Canada
18-22 June 1984 : St. Rémy-lès-Chevreuse, France 764/83

PROBLEMS IN SERVICE LIFE PREDICTION OF BUILDING MATERIALS (Mat.S) ●
Dr. G.J. FROHNSDORFF, Bldg 226, Room B-368, National Bureau of Standards, Washington, DC 20234, USA
10-12 September 1984 : Paris, France 429/83

SEMICONDUCTOR DEVICE RELIABILITY (Mat.S) ●
Dr. C.M. MELLIAR-SMITH, Bell Telephone Labs, 2525 North 12th St., Reading, PA 19604, USA
Date & Place to be announced 534/83

APPLICATION OF FRACTURE MECHANICS TO CEMENTITIOUS COMPOSITES (Mat.S)
Prof. S.P. SHAH, Dept. Materials Eng., Univ. Illinois, Box 4348, Chicago, IL 60680, USA
June 1984 : Evanston, Illinois, USA 2/82

clays may partly fill these remaining pores and block inter-pore connections, reducing permeability to 100 mD (ref. 2). If the depth and timing of such diagenetic alteration can be measured and the extent of diagenesis estimated, then prediction of the diagenetic state of undrilled sandstones may become possible and diagenesis related more closely to the timing of hydrocarbon migration and the formation of hydrocarbon traps. We present an example of a new method for estimating the date of quartz diagenesis using a combination of techniques from thin section petrography, fluid inclusion thermometry, organic geochemical thermometry and sedimentary basin stratigraphic analysis. These results suggest that quartz in the Beatrice oilfield was precipitated from moving and cooling pore fluids, at a temperature between 68 °C and 94 °C in the late Jurassic.

The Beatrice oilfield, operated by Britoil, lies in the Inner Moray Firth of the UK North Sea and contains oil reservoired in middle Jurassic sandstones[3]. Thin section and scanning electron microscope (SEM) studies of the diagenetic sequence in Bajocian reservoir sandstones indicate a specific diagenetic sequence: early-formed concretionary calcite, minor feldspar leaching and kaolinite formation, syntaxial quartz overgrowth (in at least two phases), widespread feldspar leaching and coeval kaolinite formation with minor illitization of some muscovite, minor late aggressive calcite and finally minor very late cryptocrystalline silica. The details of diagenesis will be described in more detail elsewhere[4], but the general sequence is typical of many sandstones both in the North Sea, and in other petroleum basins[5,6].

Thin section observations show that the primary permeability in some sandstone layers has been low (1–3 mD) since deposition, due to blockage of pore connections by detrital clay. These sandstones show very little diagenetic alteration and contain 3–4% potassium feldspar. By contrast, compositionally similar sandstones with high (>100 mD) primary permeabilities have experienced dissolution of potassium feldspar, and growth of authigenic quartz to form about 13%, by area, of the whole rock. Only 1% of grains in all these sandstones have suffered any pressure solution. Quartz overgrowth has uniformly affected the permeable sandstones, except in areas immediately beneath thin (5–50 cm), laterally persistent, mudstone beds, where diagenetically overgrown quartz forms a pervasive 3–20 cm thick layer, so that quartz forms about 99% of the rock. Similar layers do not occur above these mudstones. Such features, where diagenesis is limited to permeable sandstones and enhanced below impermeable layers, suggest that the diagenetic pore fluids moved through the sandstones and precipitated quartz as they cooled beneath the mudstones. It may be noted that in neutral to acid fluids, the solubility of quartz at diagenetic temperatures and pressures is dominated by temperature[7], rather than being dependent on ionic concentration[6,7], salinity[8], pressure[7], or *p*H changes[7].

During the formation of diagenetic quartz overgrowths, samples of pore fluids were trapped as fluid inclusions and as they show no signs of leakage, each is assumed to have been constant in volume and composition since its formation. These 'primary' inclusions were examined by heating and freezing fluid inclusion microscopy[9,10]. Briefly, in the case of a simple low salinity aqueous fluid, this method involves cooling an inclusion to freeze its fluid, and then warming it. The salinity of the fluid[10,11] is given by the temperature at which the ice crystals melt, and other chlorides present can be expressed as equivalent NaCl[10]. Further heating causes the inclusion to revert to a one-phase system at the 'homogenization temperature', which is the minimum trapping temperature of the inclusion and hence the fluid density[10] is determined. The true trapping temperature of an inclusion was hotter and lay somewhere along the constant density 'isochore' path through the liquid or fluid phase for the inclusion concerned. This line can be drawn from pressure-volume-temperature properties of the NaCl–H_2O fluid[10,15,16] and its measured density. In this paper the size of the upward temperature correction is constrained using an independent organic geochemical measurement of the maximum temperature

Table 1 Polycyclic alkane data used to establish maximum palaeotemperatures for the interbedded mudrocks

Sterane and triterpane ratios	Ratio* (%)	Equivalent† temperature (°C)	Comments on plots used‡
Ratio Tt No. 5	22.4	78	Well defined linear low scatter plot (Fig. 2).
Ratio St No. 5	40.8	94	Linear portion of moderate scatter plot
Ratio St No. 6	50.1	97	On shoulder of moderate scatter plot
Ratio St No. 9	38.6	87	Well defined sigmoidal low scatter plot

The following ratios have been measured for the interbedded mudstones. Triterpanes: Ratio Tt 5: 17β(H), 21α(H), 30-normoretane ÷ [17β(H), 21α(H), 30-normoretane]+[17α(H), 21β(H), 30-norhopane]. Steranes: Ratio St 5: 5α,14α,17αmethyl cholestanes (20R ÷ 20R+20S). Ratio St 6: 5α,14α,17αethyl cholestanes (20R ÷ 20R+20S). Ratio St 9: 5α,14β,17β, 20R+20S ethyl cholestanes ÷ (5α, 14β, 17β, 20R+20S)+(5α, 14α, 17α, 20R+20S) ethyl cholestanes.

* Quantitations based on *m/e* 191, 386, 217 and 218 (ref. 12, Table 1).

† Error on measurements ±6.5 °C (see text).

‡ Taken from calibration plots in ref. 12.

experienced by interbedded mudstones. This enables a pressure measurement at the time of trapping to be derived, rather than the usual stratigraphical method being used, of estimating a pressure to give a temperature. The maximum temperature recorded by the organic geothermometer may have been reached later than the time of trapping; however, since the organic temperature is only used as a constraint on the upward limit of the homogenization-to-trapping temperature correction, this will tend to give maximum trapping temperatures and maximum pressures.

In the Beatrice Field, inclusion salinities range from 8 to 17 equivalent weight per cent NaCl[11] and homogenization temperatures show a unimodal distribution around 60–78 °C, $\bar{x}$ = 68 °C (Fig. 1), and show no variation with position in the overgrowths or between different parts of the reservoir sandstones. In this case organic rich mudrocks are interbedded with the reservoir sandstones, so that the maximum burial temperature can be estimated from changes in the molecular ratios of triterpanes and steranes[12,13]. Four organic geothermometer polycyclic alkane ratios have been measured for the interbedded mudstones (Table 1). These ratios have been compared with trends established from a depth (temperature) sequence of Kimmeridge Clay Formation (North Sea 'hot shales') to determine the maximum temperature of burial for the interbedded mudstones. Although the depositional environment, and to some extent the kerogen type of the middle Jurassic interbedded mudstones in Beatrice are not identical to the Kimmeridge Clay Formation, both contain kerogens of an algal origin, bacterially degraded to a lesser or greater extent.

It should be noted that the polycyclic alkane ratios used are those that give a relatively low level of scatter in the calibration plots (Table 1, Fig. 2), and are sensitive to temperature in the range under consideration. Within our laboratories a duplicate analysis on a split sample of powdered sediment generally gives a reproducibility of ±5% on the ratios used, which corresponds to an average difference in temperature of ±6.5 °C over the temperature range under discussion. The use of the calibration curves to define the maximum palaeotemperature is entirely pragmatic, and does not rely on, or imply, any precursor-product relationship between the ratioed molecules (contrast ref. 14). Use of the Kimmeridge Clay Formation calibration plots for the middle Jurassic shales is justified by the good agreement

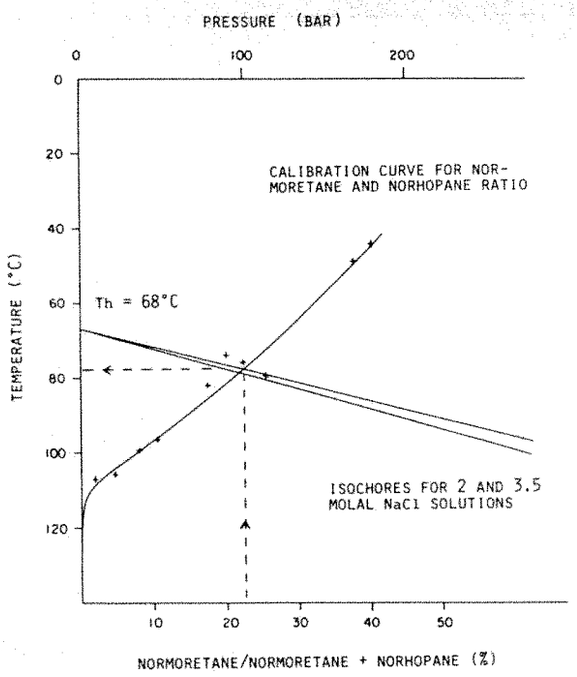

Fig. 1 Homogenization temperatures of fluid inclusions trapped in diagenetic quartz overgrowths from middle Jurassic oil reservoir sands of the Beatrice field, North Sea. Inclusions at different positions within overgrowths give similar homogenization temperatures. The spread of values may be due to slight 'necking' of some inclusions. Blank = aqueous inclusions; black = hydrocarbon bearing inclusion. Number of inclusions = 38, $\bar{x}$ (total) = 67.6 °C, $\bar{x}$ (central peak, 55 ≤ Th ≤ 80) = 67.1 °C, σ = 5 °C.

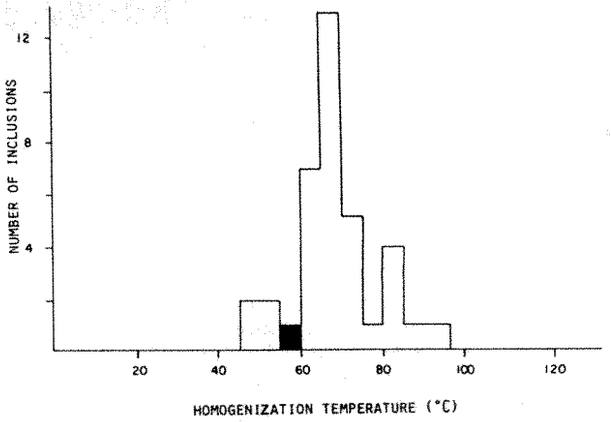

Fig. 2 Limits on pressure and temperature of diagenetic quartz overgrowth formation from volumetric properties[10] of system NaCl–H_2O. Mean inclusion homogenization temperature of 68 °C shown, together with dashed line for maximum sediment temperature of 78 °C derived from ratio Tt 5 (Table 1), calibrated using North Sea Kimmeridge Clay Formation (+) isomer data[12]. Note that triterpane ratios are calibrated against temperature rather than pressure, the correspondance of values on the pressure and triterpane scales being expected to vary for different sedimentary basins.

between the predicted temperatures for the four essentially independent ratios. Use of these four ratios indicates a minimum temperature of 78 °C and a maximum of 97 °C with a mean of 89 °C. However, the lower values derive from the calibration curves showing the least degree of scatter and are hence in practice likely to be more accurate.

We are now in a position to constrain the maximum trapping temperature at which fluid inclusions formed, and to derive the pressure at which they formed. The polycyclic alkane ratio with the best calibration curve gives a maximum temperature of 78 °C (Table 1). Thus the most probable correction of fluid inclusion homogenization temperature is from 68 °C to 78 °C, i.e. 10 °C. As the density of the trapped fluid can be calculated[15,16], and the volume of an inclusion has remained constant from its time of formation, this correction to a maximum temperature of 78 °C equates to a maximum burial pressure of 100 bars (Fig. 2)[15,16] which is equivalent to a depth of 1.0 km under purely hydrostatic loading, or of 0.4 km under purely lithostatic loading (mudrock density 2.4 g cm^{-3}). However, pressures at 0.4 km are unlikely to be lithostatic[17] and the necessary geothermal gradient of about 195 °C km^{-1} is very unlikely. Thus we are forced to conclude that diagenetic quartz overgrowth occurred at about 1.0 km depth under hydrostatic pressure, which enabled free circulation of diagenetic fluids. If the less reliable temperature of 94 °C is used (Table 1) as a maximum constraining estimate, the maximum temperature correction becomes 26 °C and so maximum pressure of quartz overgrowth increases to 240 bar, equivalent to between 1.0 km (lithostatic) and 2.4 km (hydrostatic). However, we suggest that since hydrostatic pressures are unlikely below 1.5 km (ref. 17), quartz overgrowth formation did not occur below this depth.

The shape[18] and stratigraphy[3] of the basin are known from seismic and drilling evidence. Subsidence in the Beatrice area was slow during deposition of the reservoir sandstones and remained slow until the earliest Oxfordian[19], accumulating 180 m of sediment (present-day thicknesses). Subsidence rates increased dramatically in the Oxfordian, culminating in late Oxfordian sedimentation rates of about 100 m per Myr, and accumulating 340 m of Oxfordian mudstones in all. Subsidence slowed during the Kimmeridgian[19], accumulating 200 m of mudrock, but became rapid again during the Tithonian[19], preserving 320 m of mudrock. During this late Jurassic basin subsidence a total of 860 m of mudrock accumulated in about 19 Myr (ref. 19).

We considered two extreme cases, maximum and minimum organic geothermometric temperatures, with overburden pressures derived from fluid inclusions, and equated these with overburden burial pressures generated by the present-day sediment thicknesses. Case 1: an organic geothermometric temperature of 78 °C implies, from fluid inclusion data, an overburden pressure of 100 bar. We know from stratigraphical evidence (above) that at the end of the Oxfordian, 180 m of sandstone and mudstone (density 2.6 g cm^{-3}) plus 340 m of mudrock (density 2.4 g cm^{-3}) had accumulated, giving a lithostatic load of 128 bar, plus an arbitrary additional 10 bar from seawater pressure in a sediment-starved basin, totalling 138 bar. Thus the earliest time that quartz diagenesis could have taken place was in the late Oxfordian.

Case 2 utilizes an organic geothermometer value of 94 °C (Table 1) implying an overburden pressure of 240 bar from fluid inclusion data. Stratigraphical evidence shows that a lithostatic overburden of 252 bar would have been generated by the end of the Tithonian, plus 10 bar from seawater in a sediment-starved basin, totalling 262 bar. Thus the latest time for quartz diagenesis was during the late Tithonian, the mean of these ages[19] is 150 ± 6 Myr.

To estimate geothermal gradients during quartz diagenesis we must infer sediment overburden thickness at the time[20]. In both cases we estimate that the middle Jurassic section is increased from 180 m to 200 m, as the reservoir sands at the base must have been compacted to their cemented thickness, and a 10 °C seafloor temperature is assumed. In Case 1, 340 m of mudrock would represent an initial thickness[20] of about 500 m, giving a 700 m section and a geothermal gradient of 97 °C km^{-1}. In Case 2, mudrock layers of 340 m, 200 m and 320 m would represent 370 m, 250 m and 500 m respectively[20] giving a 1,320 m section and a geothermal gradient of 71 °C km^{-1}. Although these figures are simply guidelines, they do imply a very high geothermal gradient at the end of a short period of very rapid basin subsidence (up to 100 m per Myr). We know from organic geochemistry (Table 1) that the maximum sediment temperature did not exceed 97 °C, and from electric log sonic velocity data that the maximum burial depth

of these sediments was about 3.0 km (present-day thicknesses), so that the geothermal gradient at maximum burial was only 29 °C km^{-1}. The present-day geothermal gradient from borehole measurements is 38 °C km^{-1}. Thus evidence in Beatrice suggests that the geothermal gradient varied through time[21], with very high temperatures immediately following the most rapid phase of basin subsidence, increasing only slightly, if at all[22], during the subsequent Cretaceous thermal subsidence[22] of the basin. It may be that rock microfracturing associated with basin rifting and subsidence encouraged rapid circulation of diagenetic fluids.

We have seen that diagenetic quartz forms about 13% of the reservoir sandstones; possible sources of this quartz could be: pressure solution, dissolution of silt-size quartz or of biogenic silica, feldspar breakdown, or illitization of smectite clays. The first three alternatives are inconsistent with petrographic observations. Feldspar breakdown is also insufficient, because even if dissolved feldspar had formed 10% of original grains, silica released could only have contributed 2% of the diagenetic quartz; thus we are left with a quartz supply from the illitization reaction[23–25]. This reaction occurs at about 70–90 °C[23–25], a similar temperature to that recorded by the fluid inclusions. In addition, Pearson *et al.*[26] have argued that smectite-rich muds were present in the Inner Moray Firth. Thus it seems probable that illitization in surrounding mudrocks slightly deeper in the half graben[18] released silica-rich fluids which travelled up-dip through permeable sandstone beds, and authigenic quartz was precipitated as the aqueous fluids cooled beneath mudstone roofs—with a fall in temperature from 100 °C to 80 °C the solubility of quartz decreases by 56%[7].

Thus diagenetic quartz growth occurred at several times at temperatures between 68 °C and 94 °C and pressures of 100–240 bar. Assuming that lithostatic pressure is achieved at all depths greater than 1.5 km the quartz grew in a very high geothermal gradient of 71 to 97 °C km^{-1}, immediately following episodes of rapid basin subsidence during the Oxfordian and Tithonian. Sediments reached their maximum temperatures near the end of this rifting and the geothermal gradient decreased sympathetically with postrifting subsidence. Silica was released by illitization of smectite clays and precipitated as quartz in permeable sandstone aquifers when the transporting aqueous solutions cooled.

I. M. S. was funded by the NERC and the fluid inclusion equipment supplied through NERC grant GR3/3726A. We thank M. J. Russell (University of Strathclyde) for suggesting examination of fluid inclusions, R. Archer and J. Sargeant of Britoil for helpful discussions, and Britoil and Beatrice partners for permission to publish. We thank A. S. Mackenzie for a constructive review.

Did the Dalradian slides originate as extensional faults?

N. J. Soper

R. Anderton

Department of Applied Geology, University of Strathclyde, 75 Montrose Street, Glasgow G1 1XJ, UK

Rocks of the Dalradian Supergroup[1,2] of Scotland and Ireland were deposited in late Proterozoic–early Cambrian times on what became the southern margin of the Laurentian plate, and underwent metamorphism and deformation when this margin was affected by the Grampian orogeny in the late Cambrian[3,4]. The resulting complex structure is still not fully understood, and a continuing problem is presented by the origin and significance of the 'slides', a series of ductile faults which lie sub-parallel to bedding[5]. Although numerous slides have been recognized within the Dalradian terrain[6] the term has seldom been used outside the British Caledonides. It is generally assumed that these slides are synmetamorphic and were formed during Grampian deformation. However, a consideration of their geometry, stratigraphic relationships and context now suggests that they may have been initiated as syndepositional extensional faults which were only modified, and not formed, during the Grampian orogeny.

The numerous local stratigraphic successions recognized in the Scottish Dalradian have been consolidated into a fourfold sequence comprising the Grampian (oldest), Appin, Argyll and Southern Highland Groups[1]. These have a combined stratal thickness of some 25 km and the Dalradian thus represents one of the major supracrustal sequences of the Caledonides[2]. It was deposited on a basement composed of crystalline gneisses (Lewisian) and a cover sequence (Moine) which had undergone orogenic reworking during the Grenville cycle (~1,000 Myr). Much of the Dalradian is characterized by distinctive lithologies, faciliting subdivision and correlation, and leading in turn to the recognition of many stratigraphic and structural complexities. One such is the problem posed by the 'slides'. This term was introduced by Bailey in 1910[7] for planes along which parts of the stratigraphic succession in the Ballachulish district had undergone thinning or complete excision. Slides were subsequently widely mapped within the Dalradian terrain (Fig 1) and in the Moine and Lewisian rocks of the North-West Highlands[8]. A recent tendency has been to expand the usage, inadvisably in our view, to include platy high strain zones without demonstrable stratigraphic separation[9,10].

Grampian structure is characterized by large, often recumbent primary folds which face north-west and south-east away from a central zone. Current interpretations involve upward and outward expulsion of material from this zone, the so-called 'fountain of nappes' hypothesis[11,12]. Attempts to integrate the slides into this scheme by interpreting them as ductile thrusts associated with the primary folding have not been successful (Fig. 2). As Bailey[13] was well aware, important slides such as Ballachulish and Fort William (Fig. 1) emplace younger rocks over older and thus have the geometry of 'lags' not thrusts. In

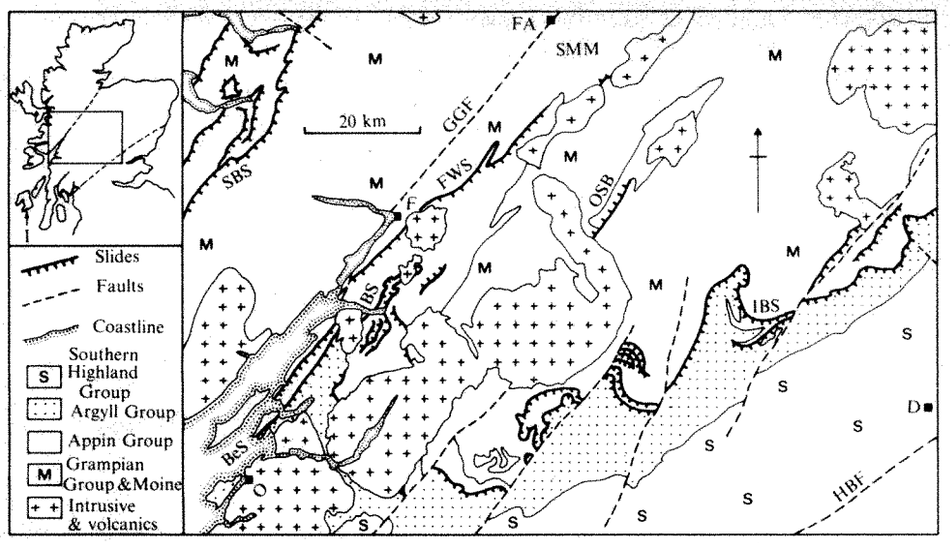

Fig. 1 Simplified geological map of part of the southwestern Highlands of Scotland showing some of the slides in the Dalradian and Moine: BeS, Benderloch slide; BS, Ballachulish slide; FWS, Fort William slide; IBS, Iltay Boundary slide; SBS, Sgurr Beag slide. Ticks are on down-dip side of slides. Box inset shows location of map. Towns: D, Dunkeld; F, Fort William; FA, Fort Augustus; O, Oban. Other localities: I, Islay; OSB, Ossian steep belt; SMM, southwestern Monadhliath Mountains. Faults: GGF, Great Glen Fault; HBF, Highland Boundary Fault. Compiled from refs 12, 27, 37–39.

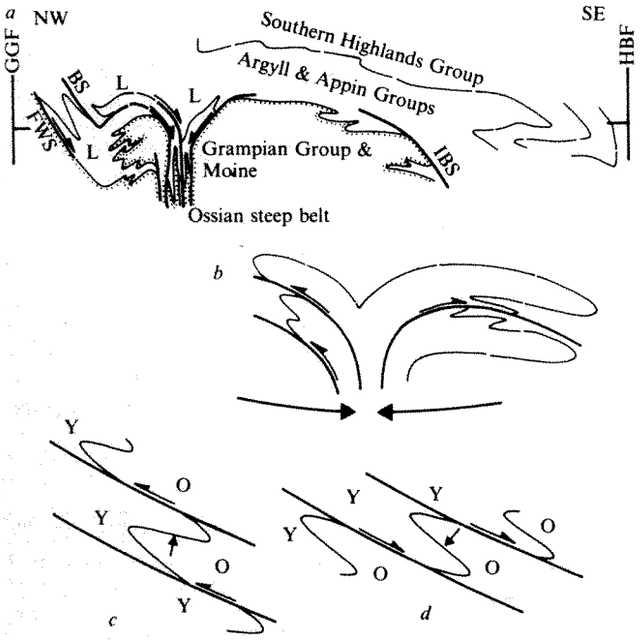

Fig. 2 *a*, Diagrammatic profile across the Grampians[12], between Fort Augustus and Dunkeld (Fig. 1). Major slides are shown by bold lines, with their displacement directions inferred from the stratigraphy indicated by half arrows and labelled as in Fig. 1. GGF, Great Glen Fault; HBF, Highland Boundary Fault; L, Lochaber Sub-group. *b*, The 'fountain of nappes' hypothesis[12] showing slide displacements opposite in sense to those shown in *a*. *c*, Lag or extensional fault geometry, as in *a*. *d*, Contractional thrust geometry, as in *b*. Y and O refer to younger and older beds respectively.

addition, associated folds often show attentuation of their right-way-up, not their inverted limbs (Fig. 2).

The concept of a lag as a thrust plane on which the upper plate was displaced less far forward than the lower seems improbable and the term is now rarely used. Lag geometry is in fact extensional, not contractional. We propose a radical solution to the problem illustrated in Fig. 2 by suggesting that the slides which show extensional geometry were initiated during Dalradian sedimentation as growth faults, not during the Grampian orogeny as thrusts.

During the late Proterozoic the Dalradian terrain evolved from a slowly subsiding stable shelf on which sediments of the Grampian and Appin Groups were deposited, into a series of rapidly subsiding fault-bounded basins (Argyll Group). This increasing instability is thought to have reflected an increasing rate of crustal stretching which eventually led, at about the beginning of the Cambrian, to rupture of the Proterozoic Super-continent[14] and birth of the Iapetus Ocean[15]. The time of rupture was marked by the extrusion of the tholeiitic Tayvallich volcanics[16] although this vulcanism appears to have been peripheral to the site of continental splitting which lay further to the south-east. It is now considered that during Argyll Group times the Dalradian terrain of the southwestern Highlands developed into a type of quasi-oceanic crust similar to that now forming at the head of the Gulf of California[17]. In this, development of a mature spreading centre is suppressed by the rapid influx of sediment and spreading takes place on a limited scale by sill and dyke injection. Thus, it is thought that there was an attempt to form oceanic crust within the present area of Dalradian outcrop, but that this was aborted and the final split took place further to the south-east.

Dalradian deposition can be viewed in the context of the McKenzie model for basin subsidence by lithosphere stretching and thermal relaxation[18–20]. During Appin Group times stretching and thinning was insufficient to allow volcanic activity, and sedimentation was able to keep pace with subsidence. More rapid stretching produced the deep Argyll Group basins[21,22]. By end-Argyll times the sediment pile had attained a maximum thickness of some 12 km and the lithosphere had thinned by a factor of about four, permitting the injection of basic magma towards the top of the sediment column. An interpretation of the lateral thickness and facies changes within the Argyll Group suggests that this stretching was accomplished by major *syn*-depositional faults, with throws of up to several kilometers and an across-strike spacing of tens of kilometres, dividing the area into blocks and basins[22]. Current ideas on extensional faulting suggest that such faults can often be listric in form, flattening out at a depth of 8–12 km[19,20,23,24]. This would be the depth of the lower part of the Appin Group by mid-Argyll times. Figure 3 illustrates these faults schematically; some of them we suggest are now represented by slides. Later subsidence to accommodate the Southern Highland Group may have been largely thermal, following abandonment of the incipient rifting centre, no further extension being required.

It has always been assumed that the slides are of Grampian age, associated with the primary deformation. Many carry a penetrative fabric and some coincide with a change in facing of early folds[6,25,26]. These must either have been initiated during the Grampian deformation or, if earlier, suffered reactivation. On the other hand the Benderloch slide, for example, has the regional fabric superimposed obliquely across it[27] and appears to be pre-Grampian. As Litherland[28] pointed out, the slide coincides with a major facies change in the Argyll Group which thickens rapidly across it to the south-east. Our contention is

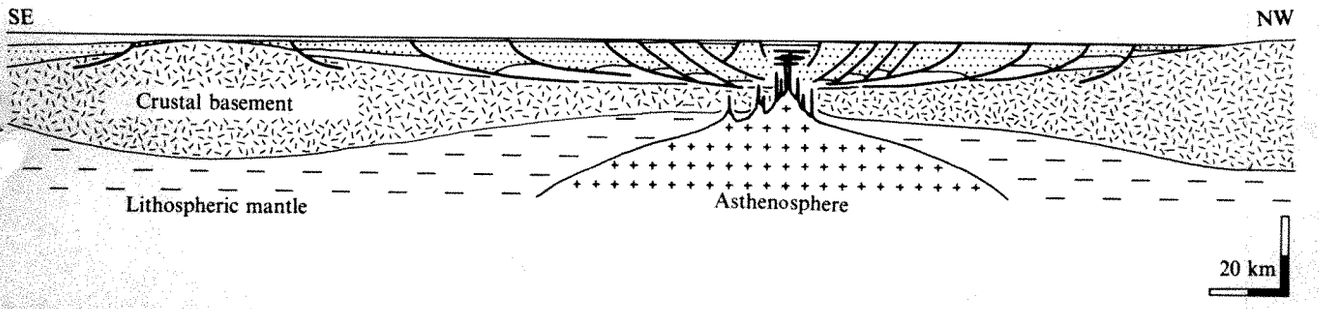

Fig. 3 Sketch illustrating the crustal structure of the Dalradian terrain, in late Argyll Group times, showing listric and other normal faults. Continental crust is on the verge of rupturing with the formation of quasi-oceanic crust by sill and dyke emplacement. Crustal stretching subsequently ceased here, the complete failure of the Laurentian–Baltic plate taking place at another site of crustal attenuation to the south-east of the area shown on this diagram. Ornament for Appin and Argyll Groups is as shown on Fig. 1. Older basement rocks are not differentiated.

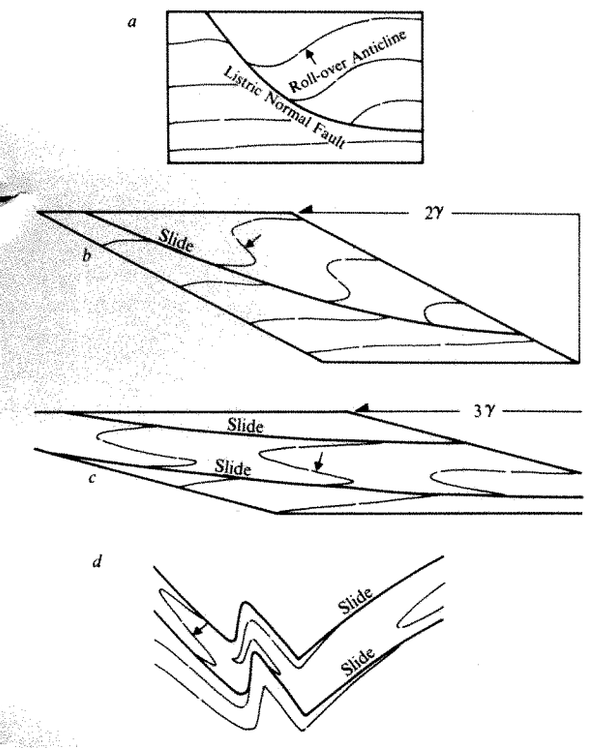

Fig. 4 Diagrams illustrating the geometrical possibility of deriving Grampian slide and primary fold geometry by the superimposition of simple shear strain on early extensional structures. *a*, Listric normal fault and associated roll-over anticline[29]. *b*, Passive rotation of slide plane and bedding under a shear strain of 2γ. *c*, Under 3γ 'primary' recumbent folds are produced. Two slide zones are shown. *d*, Secondary refolding of *c* produces a profile comparable to that of the southwestern Monadhliath Mountains (compare ref. 30, Fig. 3).

that slides such as the Benderloch, which emplace younger rocks over older and thus have extensional geometry, started life as listric growth faults and either behaved entirely passively during Grampian deformation, or were reactivated. Studies are needed to test whether displacements inferred from fabrics and folds associated with particular slides are compatible with the displacements required by the stratigraphy.

Figure 4 illustrates that the hypothesis is geometrically realistic, and can also account for those associated folds which have their 'wrong' limb attenuated. We start with a listric normal fault and roll-over anticline, as seen in many examples revealed by reflection profiling of extensional continental margins[29]. Accepting the view that Grampian deformation in Scotland did involve the expulsion of material north-west and south-east from a central zone (which coincided approximately with a major depocentre) we model the deformation as simple shear with an opposite sense of displacement to that of the growth fault. Passive rotation of the material planes (bedding and fault) under quite modest shear strains produces folds with their right-way-up limbs apparently attenuated at the slide. Secondary refolding generates a geometry comparable with that of the published profile of the southwestern Monadhliath Mountains[30,31].

Our hypothesis could throw light on unexplained features of Highland geology. For example the Ossian steep belt[12] (Fig. 2) could represent a highly compressed graben. The Loch Skerrols 'thrust' in Islay[32] marks the western margin of the Grampian orogenic belt against the north-west foreland, a position analogous to that of the Moine thrust zone to the north, a major contractional structure. However, the Loch Skerrols displacement brings Argyll Group rocks in the hanging wall against older Bowmore sandstone and thus appears to be extensional. It may have developed on the site of a major basin-margin fault.

Structures referable to the major phase of extension which affected the sub-Dalradian basement in the late Proterozoic, and which might have survived Grampian–Caledonian overprinting, should be sought. Extensional displacements at depth would generate ductile fabrics difficult to distinguish from those associated with subsequent compressional events. The reactivation of syndepositional faults in compression may well represent an important mechanism of upper lithosphere shortening in zones of continental convergence[33].

Finally, we point to the apparent coincidence in time between the Morarian pegmatite 'event' which affected the Old Moine basement at around 750 Myr[9,34], and the onset of Grampian–Dalradian sedimentation. The traditional interpretation of the Morarian as a late Grenville, pre-Grampian orogenic event (equivalent to the now-discredited Carolinides of north-east Greenland[35]) is difficult to sustain without clear evidence of compressional structures or syntectonic metamorphism. Although it has been proposed that these pegmatites are associated with ductile shear zones[9], they are clearly dilational and lack synkinematic crystallization fabrics[36]. We suggest that they were formed during a major phase of crustal stretching and enhanced heat flow associated with the onset of cover sedimentation.

The gradual decline of the dinosaurs—fact or fallacy?

Dale A. Russell

Paleobiology Division, National Museum of Natural Sciences, Ottawa, Canada K1A OM8

Both great dinosaurian orders (Saurischia and Ornithischia) were major components of terrestrial vertebrate faunas for ~150 Myr. The prevailing view is that dinosaurs attained an evolutionary acme late in the Cretaceous, after which they gradually declined in taxonomic diversity over ~10 Myr to their extinction 63 Myr ago[1–6]. The postulated decline is usually supported by comparing diversity levels in 76 Myr-old and 64 Myr-old dinosaurian assemblages from North America. The resulting differences in diversity have never been compared, however, with those observed between older dinosaurian assemblages, when their extinction was not imminent. I show here that, taken as a whole, the known fossil record of North American dinosaurs shows no evidence of a decline in taxonomic diversity lasting several million years or more before their extinction.

The fossil record of dinosaurs preserved in Triassic to Cretaceous strata in North America is unsurpassed on other continents in terms of the number of specimens that have been recovered, and the degree to which they are representative of successive phases of dinosaurian evolution[7]. Thus, a possible terminal Cretaceous decline in diversity is assessed here through a compilation of all of the known families and genera of North American dinosaurs[8] (see Table 1 and Fig. 1). The data are based on skeletal materials collected largely from the eastern Rocky Mountains and adjacent plains, and from sediments associated with the Newark Rift System extending from Nova Scotia to North Carolina. Only late Triassic, late Jurassic and late Cretaceous terrestrial reptilian faunas have been relatively well sampled. These circumstances, together with the fact that many available collections are inadequately studied, imply that fewer than one-half of the dinosaurian genera which at one time or another were indigenous to North America have been recorded. Nevertheless, the compilation suggests that dinosaurs increased in diversity through the Mesozoic era. Data based on mammalian material collected from the same lithostratigraphic units[9] show similar trends (the differences in slopes of linear regressions for dinosaurian and mammalian genera and families against time are not statistically significant). Dinosaurs show no more evidence of a late Mesozoic decline than do mammals.

Rarefaction analyses[10,11] should be carried out on dinosaurian (and contemporary mammalian) assemblages to remove the effect of sample size on observed diversity. This can seldom be done because of the lack of available data. It is possible, however, in the case of the most diverse dinosaurian assemblage known, that occurring in sediments deposited 13 Myr before the end of the Cretaceous in the vicinity of Dinosaur Provincial Park, Alberta. This locality has also yielded the largest number of dinosaurian skeletal fragments known from any area of badlands of comparable size[12–14]. A rarefaction trend (Fig. 2) was plotted, based on the number and proportions of generically identified, articulated specimens from the Alberta locality.

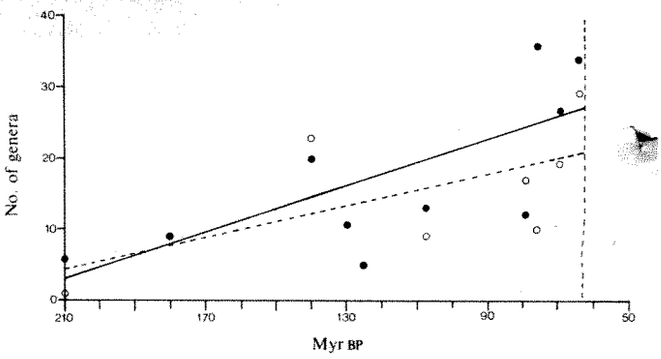

Fig. 1 Generic diversity of North American dinosaurs (closed circles) and mammals (open circles) plotted against time measured in Myr BP. The regression line for dinosaurs (solid line) is $g = 37.1 - 0.16t$, $r = -0.71$, and for mammals (broken line) $g = 27.2 - 0.11t$, $r = -0.61$, where g = number of genera and t = time in Myr. The vertical broken line represents the Cretaceous–Tertiary boundary plotted at 63 Myr BP.

Collections of dinosaur skeletal materials from younger assemblages are smaller[15] and less well studied. The diversity contained within one relatively well studied collection of 20 specimens in the Los Angeles County Museum, from sediments deposited in eastern Montana ~1 Myr before the extinctions[16–20], falls within the 95% confidence interval for the rarefaction curve calculated for the older Canadian site (asterisk, Fig. 2). This is despite the fact that the older locality has been shown to contain an ecological gradient and therefore may have yielded a more than usually diverse assemblage[12–14]. Diversity levels were evidently maintained in the terminal Cretaceous sample from Montana despite environmental changes in the wake of a major retreat of the midcontinental sea which occurred ~1 Myr previously[21,22], but did not recur at the end of the dinosaurian era[23]. The diversity contained within another small collection of a more inland facies from the Scollard Formation of Alberta[24,25] (with apparently 7 genera distributed among 17 specimens) may be similar to that of the Montana sample. No other assemblage of terminal Cretaceous dinosaurs is sufficiently well studied to serve as a useful basis for comparison. The

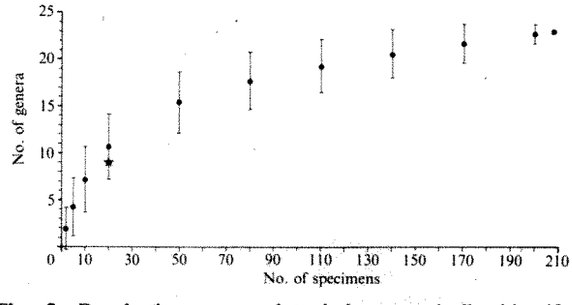

Fig. 2 Rarefaction curve plotted for generically identified dinosaur specimens from Dinosaur Provincial Park, Alberta, dating from ~13 Myr before the terminal Cretaceous extinctions. The asterisk indicates the position of the Hell Creek Fossil Field subsample in the collections of the Los Angeles County Museum dating from ~1 Myr before the terminal Cretaceous extinctions.

Marine stage (continental stage)	Absolute age	No. of genera		No. of families	
		Dinosaurs	Mammals	Dinosaurs	Mammals
Upper Maastrichtian (Lancian)	~64	34	29	19	16
Upper Campanian–Lower Maastrichtian (Edmontonian)	~70	27	19	13	13
Upper Campanian (Judithian)	~76	36	10	15	8
Lower Campanian (Aquilan)	~80	12	17	8	11
Aptian–Albian (Paluxian)	~108	13	9	10	7
Valanginian	~125	5	—	5	—
Kimmeridgian–Portlandian	~140	20	23	13	8
Hettangian–Pleinsbachian	~180	9	—	7	—
Carnian	~210	6	1	5	1

The absolute age is given in Myr BP. Mammalian generic diversity levels are probably exaggerated for Kimmeridgian–Portlandian time due to the assignment of separate names to disassociated upper and lower dentitions[39].

Cloverly assemblage from Wyoming and Montana[26–29], which predates the end of the Cretaceous by ~45 Myr and contains 6 genera distributed among at least 50 specimens, is evidently of low diversity for reasons other than its proximity in time to the Cretaceous–Tertiary boundary.

The record of dinosaurian diversity through Mesozoic time in other parts of the world is less complete. A sequence of continental strata in Mongolia, although not well dated, is clearly of late Cretaceous age[30–32]. A succession of three dinosaurian assemblages in these sediments shows no evidence of a decline in diversity[30]. Other potentially excellent continental records[33–35] will require more study before broad trends in dinosaurian diversity become apparent. It is clear, however, that dinosaurs were distributed around the world during terminal Cretaceous time[36].

This compilation of dinosaurian families and genera from Mesozoic strata in North America seems to be in general conformity with contemporary diversity trends seen in terrestrial mammals, marine invertebrates[37] and terrestrial plants[38]. There is no compelling evidence for a terminal Cretaceous decline in dinosaurian diversity on a time scale of millions of years.

I thank F. Asaro for suggesting that a compilation similar to that of Table 1 be made and D. M. Raup for the rarefaction analysis shown in Fig. 2. I also thank W. Alvarez, P. J. Currie, P. Dodson, J. S. McIntosh and K. A. Pirozynski for critically reviewing the manuscript. D. Baird, M. K. Brett-Surman, K. Carpenter, P. Dodson, P. M. Galton, J. R. Horner, W. Langston Jr, R. A. Long and J. S. McIntosh generously provided information on the affinities of numerous dinosaurian specimens.

Courtship feeding increases female reproductive success in bushcrickets

Darryl T. Gwynne*

Department of Zoology, University of Western Australia, Nedlands, Western Australia 6009

Parental investment theory suggests that investment by males through courtship feeding of their mates may represent an important source of nutrition which increases female fitness and ultimately influences patterns of sexual selection[1,2]. In certain insects males provide nutritional products from reproductive accessory glands during mating; these are either eaten by the female or are absorbed in her genital tract[2,3]. Male bushcrickets (Orthoptera: Tettigoniidae) feed their mates with an elaborate spermatophore consisting of a spermatophylax, which is eaten by the female after mating, and a sperm ampulla, eaten after the ejaculate has emptied[4,5]. Studies of bushcricket mating systems have indicated that spermatophore nutrients are important to females—females prefer to mate with males able to supply larger spermatophores[6]—and field studies of species with very large spermatophores have revealed a role-reversal in reproductive behaviour, with females aggressively competing for males capable of producing spermatophores[7,8]. Although radiolabelling experiments (with several insect species) have demonstrated that male-derived nutrients are incorporated into eggs[3,9–11], these studies do not demonstrate that this sort of courtship feeding enhances female fitness. Here I report the results of an experiment which shows that feeding on the spermatophore enhances the reproductive success of female bushcrickets (*Requena verticalis* Walker) by increasing the numbers and size of eggs produced.

In *R. verticalis*, radiolabelled nutrients from the spermatophore are incorporated to a large degree into maturing eggs[3]. A previous study of this species showed no influence of the amount of male-derived nutrition on fecundity[5]. All females

Subjects for the experiment were collected as late instar females in Perth, Western Australia, and reared to adulthood in the laboratory (14 h light: 10 h dark at 25 °C). Nymphs were all fed on a diet of rolled oats, tropical fish food and pollen (17% crude protein) and fresh carrot. Adult females were measured (pronotum length in mm (±0.01 mm)) and mated 7–15 days after the adult moult, over a 41-day period in February–March 1983. For treatment 0, the intact spermatophylax was removed from the ampulla with forceps before the female grasped it (females remove the spermatophylax from the ampulla a few minutes after mating[5]). The female was then placed in a glass tube for 4–5 h (sufficient time to allow sperm supplies to empty) to prevent her from removing the sperm ampulla prematurely[5]. After releasing the female from the tube, I removed the empty ampulla before she could consume it. Additional spermatophylaxes for treatments 3 and 7 were obtained from both treatment 0 matings and other matings set up at the same time. These spermatophylaxes were fed to females within an hour of being produced. Spermatophylaxes received by each female from treatments 3 and 7 were derived from different males. Females from all matings were housed in 1-l jars placed over the oviposition substrate (dry sand) and fed on rolled oats (12% crude protein) and fresh carrot. Eggs were collected from the sand at 7, 14, 21, 28 and 30 days post-mating. Dissection of females revealed that they all had extensive fat body in the abdominal cavity. SS, sum of squares; MS, mean of squares, d.f., degrees of freedom.

* Mean adjusted for the effects of covariates, day mated and pronotum length.

in that study received a high protein diet, with some females receiving one extra spermatophylax at mating. For bushcrickets, limited access to high protein food sources (several subfamilies)[12,16] and up to 12 matings, and thus spermatophores, per female (*Anabrus simplex*)[16] have been documented in nature. Therefore, in the present study females were given a wide range of the male nutrient contribution and were maintained on a lower (12%) protein diet.

Four treatments were established in which the amount of male-derived nutrition was manipulated but the amount of sperm and other ejaculatory materials received by females was controlled. Individuals were all mated once and all matings were conducted over a 41-day period. Treatment numbers represent the number of spermatophylaxes females consumed: hence, treatment 0, the intact spermatophylax was removed after mating and the empty ampulla after insemination (that is, females received no oral nutrition from the male); treatment 1, normal matings in which females were allowed to consume the spermatophylax and ampulla; treatment 3, females were fed two additional spermatophylaxes, one every 6 or 7 days, during the first 14 days after a normal mating; and treatment 7, females were fed six additional spermatophylaxes, one every 2 or 3 days, during the first 14 days following a normal mating. All individuals were allowed to oviposit in dry sand for 30 days after mating. This time period was sufficient to allow the incorporation of a large amount of male-derived nutrition into mature eggs[3]. Females were then killed, numbers of mature ovarian eggs (those with a chorion) were added to the counts of eggs laid and the spermathecae were checked for the presence of sperm. Of 54 individuals, 51 had ample sperm supplies; the three females without sperm were discarded from the analysis (additional details of methods are presented in Table 1 legend).

Analysis of variance of egg number by treatment with size (pronotum length) and day mated (1–41) as covariates revealed a highly significant effect: the number of eggs produced increases with the amount of male-derived nutrition eaten (Table 1). All pairwise comparisons of treatment means were significantly different (Student–Newman-Keuls (SNK) tests, $P<0.05$). The

Table 2 Effect of number of spermatophylaxes eaten on egg weight

No. of spermatophylaxes eaten	0	1	3	7
Mean weight of 5 eggs (mg) ($\bar{x}$+s.e.)	9.7±0.16	10.0±0.18	10.3±0.18	10.6±0.21
Sample size	14	12	12	13

Treatment		4.44	3	1.48	3.48	0.024
Covariates:						
Day mated	−0.005	0.12	1	0.12	0.27	0.604
Pronotum length	0.22	0.59	1	0.59	1.40	0.245
Explained		5.78	5	1.16	2.72	0.031
Residual		19.2	45	0.426		

consumption of the spermatophore meal in the female's first mating represents an increase in numbers of eggs produced of some 40% (compare treatments 0 and 1, Table 1). The covariates, size and day mated, each had a significant effect (positive and negative, respectively) on egg number (Table 1). A preliminary analysis of covariance demonstrated that the slopes of size and day mated on egg number did not differ between treatments ($P>0.05$).

Analysis of variance of egg weight (mean weight of groups of five eggs for each female) by treatment with size and day mated controlled revealed a significant effect of treatment; egg weight increases with the amount of male-derived nutrition eaten (Table 2). Only one pairwise comparison (0 and 7) showed a significant difference (SNK test, $P<0.05$). Neither size nor day mated had a significant effect on egg weight (Table 2). The slopes of these two covariates on egg weight did not differ between treatments (analysis of covariance, $P>0.05$).

Thus, an increase in the number of spermatophores eaten not only enhances female fecundity but also increases the size of the eggs she produces. Larger egg size in insects is known to correlate with several components of offspring fitness[13]. Although an increase in either egg size or number *per se* may, in certain circumstances, not represent an increase in reproductive success[13,14], a concomitant increase in both probably represents increased fitness of females.

Investment in the spermatophore can be regarded as 'parental'[15] as the investment not only enhances female fecundity but is also a cost to the male[1,15]. A spermatophore represents a weight loss of up to 40% for the male bushcricket[7]; in *Orchelimum delicatum* there is a reduction in the size of the spermatophore produced in a second mating 24 h after the first[7]. A cost would be reflected in a decreased ability to invest in further offspring[1] if a reduction in this food donation to the female reduced the numbers and size of those eggs subsequently fertilized by the male.

The advantage to females of obtaining additional spermatophore nutrients provides an adaptive basis for female discrimination of males observed in some species; female *R. verticalis* prevent insemination when no spermatophylax is received from the male[5] and female *Conocephalus nigropleurum* prefer to mate with males able to supply larger spermatophores[6]. Thus, both selection on males to produce fitter offspring and intersexual selection (female choice) may have contributed to the evolution of one of the most elaborate sperm packages known.

Stress-induced alignment of division plane in plant tissues grown *in vitro*

Philip M. Lintilhac & Thompson B. Vesecky

Botany Department, University of Vermont, Burlington, Vermont 05405, USA

The architectural nature of cell patterns in plants, which are visible under the light microscope, offers strong intuitive evidence for a structural relationship between mechanical forces acting through the tissue and cell wall orientation at cytokinesis. However, a direct relationship between the two has never been convincingly established. We find that compressive forces at intensities between 500 and 800 mg mm^{-2} can induce a conspicuous spatial ordering of division activity when applied to sterile plant tissues during continued growth in culture; this results in cambium-like areas of cell wall co-planarity which are clearly distinguishable from the characteristically disorganized growth of unstressed regions of the explant, and implies the presence of an intracellular structural–mechanical sensor capable of directing the installation of the new cell partition. The experiment reported here, in which compressive forces were applied to plant tissue growing *in vitro*, provides an example of mechanical control of division plane.

Cell division in multicellular plant tissues is characterized by a telophase structure known as the cell plate[1] which is an early stage of partition wall formation. The role of cell plate orientation in the development of form in plants is clear as repeated parallel divisions increase the number of cells in a file, thereby contributing to the directional accumulation of tissue mass. Such file cells also tend to elongate perpendicular to the new cross walls, which means that the overall cross-wall orientation of the cells comprising an unexpanded organ also predicts the direction of elongation of the organ as a whole.

We propose that the final orientation of the cell plate is adjusted according to extracellular stress–mechanical cues until it assumes an orientation which is architecturally functional, that is, maximally protected from shear[2]. According to our hypothesis, mechanical forces transmitted through the tissue are directly sensed at the cellular level, so that each dividing cell responds to its own stress–mechanical environment with the erection of an appropriately oriented partition wall.

If this is true, then dividing cells subjected to external forces acting in a given direction should respond by orienting new partition walls consistently with respect to the direction of force propagation. This has been shown for whole plants *in vivo*[3], but never for isolated tissues growing *in vitro*. Cultured plant tissues subjected to exogenous forces should provide particularly clear-cut support for this hypothesis because: (1) They may be considered to be largely stress-relieved after explanting and transfer to sterile culture, so that any induced order can be unequivocally attributed to the stresses and strains generated by the experimentally applied forces. (2) The physiological environment of growth can be more closely controlled, making it more difficult to attribute induced order to concerted hormonal responses and morphogen gradients which could be organized by a whole plant. (3) Tissues can be chosen which are virtually homogeneous and devoid of structurally specialized cell types which could modify the transmission of forces through the tissue. The freshly explanted pith tissue used here is homogeneous and regular, but not ordered into ranks and files as are the products of an *in vivo* vascular cambium (Fig. 1*A*). Thus, the experimentally induced co-planarity cannot be ascribed to pre-existing order in the explant.

Fresh pith cores weighing ~25 mg were taken from the second internode of greenhouse-grown *Nicotiana tabacum L.* (Fig. 1*A*) with a square coring tool, providing a square pith explant 1 mm on a side and of indefinite length. The apical centimetre of this explant was removed and 'planted' in its original orientation in an agar-solidified medium, which was then layered with 50 ml of identically constituted liquid medium. We used a standard defined medium[4] with added indole 3-acetic acid (IAA; 10 mg l^{-1}) and kinetin (0.4 μg l^{-1}), and incubated the explants at 28 °C.

After a 24-h initial accommodation period to allow for a transient burst of elongation growth, compressive forces were applied to the tissue by means of a pneumatic forcing frame

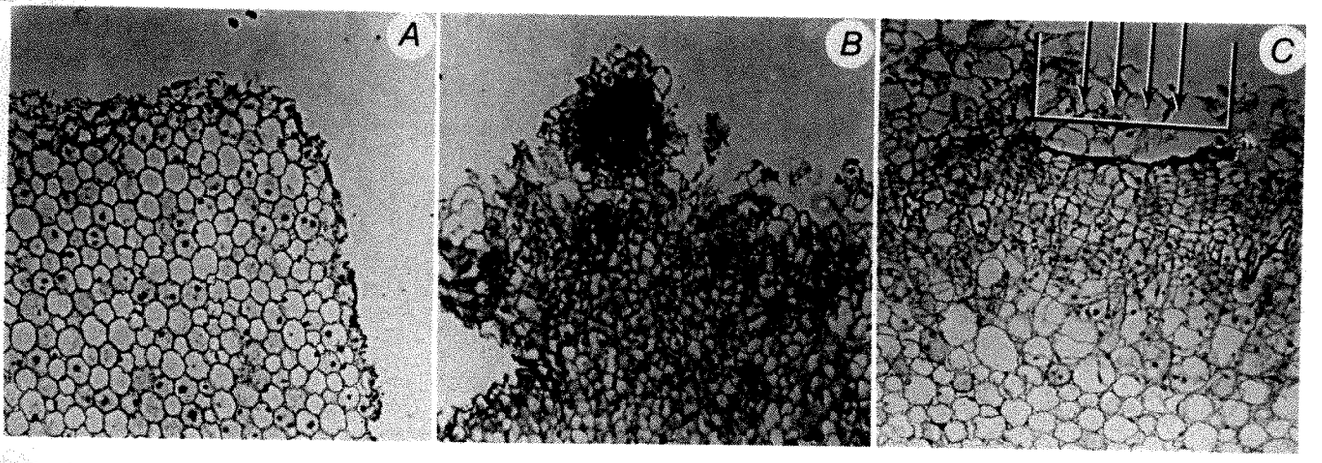

Fig. 1 Transverse sections of cultured and uncultured explants of *Nicotiana* pith. ×100. *A*, The initial condition of the explant before transfer into sterile culture. Note the lack of differentiated structural or vascular elements and of regular, co-oriented partition walls. Interfascicular cambium is absent from this level of the stem. *B* And *C* show aspects of an equivalent explant after 5 days in a standard defined medium. *B* Shows unrestrained callus proliferating from one corner of the explant; note the random proliferation, with little evidence of repeated divisions in any one plane. *C* Shows another area of the same section, growing under continuous compressive stress applied through a narrow Teflon interface (arrows). Note the radially aligned files of cells extending from the original pith core out to the interface surface. These files of cells result from repeated, co-planar divisions of pith-derived cells, constrained by 0.075 bar compressive stress. Parallel development gives the region a cambium-like appearance. Some evidence of xylem differentiation can be seen at a level 6–8 cells internal to the interface. Some loose callus cells have slumped into the interface area during fixation.

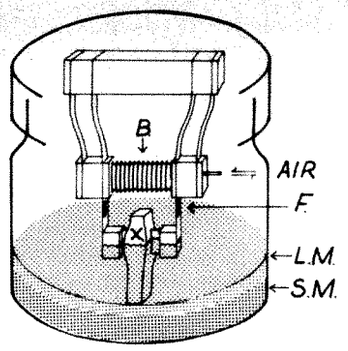

Fig. 2 Schematic representation of a pneumatic forcing-frame developed for continuous, long-term compressive loading of tissues in sterile culture. The sterilizable assembly hangs from the lid of a standard culture dish. Bellows B is the actuator, connected to an external peristaltic pump which reversibly meters small amounts of air into the bellows. A continuous matching of the applied force to a preset force set-point is accomplished by an external feedback control circuit (not shown). Forces applied to the tissue are measured by resistive strain gauges at F, which act as force transducers. The tissue explant is partly embedded in a layer of solidified medium (SM), over which is poured a layer of liquid medium (LM). Partly submerged Teflon interface pieces attached directly to the force transducers apply forces directly to the tissue at the meniscus. Each of the opposed contact surfaces measures 10.0×0.5 mm.

(Fig. 2). In the experiment reported here the frame squeezed opposing vertical faces of the explant.

A rapidly developing callus growth at the air–liquid meniscus soon supported the entire load generated by the forcing frame. At the end of the experiment, forces of $0.75g$ were supported by an area of callussed explant surface somewhat larger than 1 mm^2, generating compressive stress intensities of 0.075 bar at the contact surface. After 5 days of active proliferative growth while being subjected to continuous, controlled compressive stress, the explant, now weighing ~250 mg, was fixed and sectioned in a plane perpendicular to its long axis.

The effective resolution of force measurement in our system is ±10 mg. There is also a cumulative error due to instrumental drift, which in the experiment presented here resulted in the gradual increase in applied force from an initial value of 500 mg to a final value of 750 mg after 5 days. These instrumental difficulties, together with the fact that not all explants are completely alike or grow equally rapidly and uniformly, have prevented us from obtaining a true picture of the repeatability of our result. Nevertheless, in all explants where compressive stresses between 500 and 800 mg mm^{-2} were applied to actively dividing cells, co-planar divisions were evident, although not always extending uniformly across the interface surface. Further development of our instrument and methods should allow us to routinely effect cell alignments like those illustrated here.

Fig. 1*C* shows that co-planar divisions immediately internal to the interface surface accumulated to a depth of 10 ranks of cells, giving the load-bearing region of the explant an appearance similar to that produced by cambial activity. By comparison, unloaded regions of the same section show the largely disorganized callus growth behaviour typical of this tissue in this medium (Fig. 1*B*).

The proliferation of the explanted tissue at the meniscus is presumably due to an interplay of factors from the medium and from the air which provide an optimum of nutrition, gas exchange and surface effects. However, the proliferation encircles the explant at the meniscus, whereas the region of co-planar divisions is restricted to those parts of the proliferation supporting the directional compressive forces generated by the forcing frame. This implies that mechanical stimulation is the principal effector responsible for the co-planar orientation of newly installed cell partitions in this experimental system.

Although many plant tissues, when explanted into sterile culture, can be induced to undergo a normal morphogenesis, most will revert temporarily to a disorganized growth form termed callus. Tobacco pith is one of these. We propose that this behaviour is due to the loss of the *in vivo* mechanical environment of growth, which no amount of *in vitro* nutritional or hormonal manipulation can restore. The experiment reported here is a direct attempt to re-establish this lost mechanical environment. The distribution, coherence and regularity of divisions in the example presented here are difficult to explain by a diffusively maintained prepattern or positional signal[5] which would have to be focused through the tissue and interpreted by the individual cells in such a way as to orient new partition walls with strict regard to external landmarks.

A mechanism responding directly to stress–mechanical stimuli can refer to the intracellular physical effects of the stresses and strains propagating through the tissue for local spatial cues, and requires only that each cell is provided with an intracellular sensor which can react in predictable ways to the slight cellular dimension changes resulting from the directional transmission of force through the tissue[2]. The regularity of the response then becomes simply a function of the predictability of stress propagation through the tissue, which in turn depends on the quality of the mechanical coupling of the tissue provided by the shared cell walls. The need to assign unique positional values to each cell[5] disappears, as the stress–mechanical environment of each cell is necessarily location-specific.

Throughout the plant kingdom, growth and development provide repeated examples of highly ordered and conserved division sequences which offer *prima facie* evidence of structural adaptation at the tissue level. Although this is one of the oldest and most recurrent themes of plant science[6,7], a solid experimental and theoretical basis for understanding the structural sensitivities of individual plant cells is absent from the literature.

We hope that the direct manipulation of the plane of division in actively growing plant tissues *in vitro* will lead to a more precise understanding of developmental events in plants by providing a tool for the dissection of the constraints which govern cell wall patterns.

Gastrulation and formation of the neural plate are major steps in early vertebrate embryogenesis. Although morphogenetic movements leading to the formation of the primary germ layers have been extensively described[1–3], the mechanisms governing migration of mesodermal cells and their interactions with ectoderm remain ill-defined. A large body of evidence indicates that fibronectin (FN), a high molecular weight cell-surface-associated glycoprotein, promotes cell adhesion and cell migration throughout embryogenesis[4–6]. FN has been detected at an early blastula stage in *Pleurodeles waltlii*[7]. We now show that FN is a component of a dense fibrillar matrix underlying the blastocoel roof; in contrast, the exterior surface of the embryo

0028–0836/84/040364—04$01.00

is devoid of FN. Microsurgical inversion of part of the blastocoel roof does not prevent mesodermal cell migration except at the site of inversion where no FN matrix is available. Perturbation experiments using antibodies to FN demonstrate that the invagination of presumptive mesodermal cells does not occur when the monovalent antibodies are injected before or at the onset of gastrulation; on the other hand, the formation of a neural plate is not prevented when late gastrula stage embryos are treated with antibodies to FN. We conclude that the presence of FN is required for cell migration during gastrulation.

Antibodies directed against chick FN have been previously used to demonstrate the presence of FN on the inner surface of the ectoderm of gastrulating *Pleurodeles* embryos[7]. Specific antibodies to *Ambystoma* mexicanum plasma FN were prepared (Fig. 1) to improve the immunofluorescence staining. In whole-mount ectodermal explants, we could visualize a dense fibrillar FN-rich extracellular matrix on the inner surface of the blastocoel roof (Fig. 2*a–c*). In contrast, no FN could be detected (Fig. 2*c*) on the outer surface of the embryo.

To probe for a potential role of the extracellular matrix in gastrulation, part of the roof of the blastocoel was grafted inside-out near the site of invagination (Fig. 2*d*). In these embryos pioneer migrating mesodermal cells avoided the grafted region. At a later stage, the confluent mesodermal layer that formed uniformly beneath the ectoderm was found to overlap this region without adhering to it (Fig. 2*e*).

Injection of monovalent antibodies to FN into the blastocoel cavity just before gastrulation prevented the invagination of mesodermal cells. The gross appearance of the embryo (Fig. 2*f*) was strikingly different from that of the control (Fig. 2*g*). The blastocoel roof gave rise to a highly convoluted structure, possibly because it could not undergo normal epiboly. The lower surface corresponded to the non-invaginated presumptive mesodermal and endodermal cells. Only a very few pioneer migrating cells were found on the inner surface, which remained mostly naked (not shown).

Antibodies to FN were found to bind to the FN fibres at the surface of the blastocoel for at least 12 h after injection (not shown). Table 1 summarizes the results obtained at different stages before and during gastrulation. When monovalent antibodies to FN were injected in the blastocoel cavity at the blastula or early gastrula stages, a clear-cut inhibition of gastrulation was observed within 6 h. This phenomenon lasted for 24 h and led to abnormal development of the embryo as shown in Fig. 2*f*. Interestingly, when gastrulation was almost completed, injection of antibodies to FN did not affect neurulation. Some embryos did not survive 24 h; this was not due to a nonspecific toxic effect of the antibodies, since no cytolysis was observed

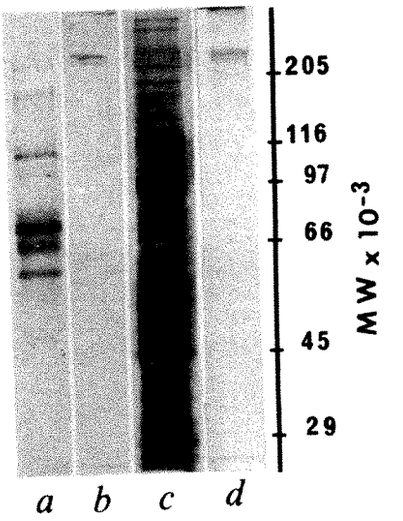

Fig. 1 Specificity of antibodies directed against *Ambystoma mexicanum* FN. *Ambystoma mexicanum* plasma FN was purified by affinity chromatography on a gelatin Sepharose column[20] and high titre (1:6,000 dilution for immunofluorescence labelling) antibodies were raised in rabbits. IgG and Fab' monovalent fragments were prepared according to Brackenbury *et al.*[21], 10% polyacrylamide gel electrophoresis[22] and immunoblotting[23]. *a*, *b*, Plasma from adult *Ambystoma mexicanum*. *a*, Several major bands are detectable after Coomassie blue staining. *b*, Only one close doublet of molecular weight (MW) 220,000 was revealed after transfer to nitrocellulose sheets, followed by incubations with rabbit IgG anti-FN (2 μg ml^{-1}) and Protein A coupled to peroxidase (5 μg ml^{-1}) and revealed with diaminobenzidine in the presence of H_2O_2 (standard MWs correspond to myosin (205,000), galactosidase (116,000), phosphorylase *b* (97,000), bovine serum albumin (66,000), ovalbumin (45,000) and carbonic anhydrase (29,000). *c*, *d*, Electrophoresis of *Pleurodeles waltlii* mid-gastrulae embryos solubilized in SDS sample buffer[22]. *c*, Coomassie blue staining shows more than 50 bands. *d*, Only one doublet of MW 220,000 reacted with anti-FN antibodies. The protein recognized both in the plasma and in the protein mixture extracted from embryos co-migrated with purified plasma FN. These antibodies were considered to be monospecific and were not used routinely as affinity purified because their titre decreased considerably with this procedure which prevented inhibition experiments.

Table 1 Effects of monovalent fibronectin antibodies on the gastrulation of *Pleurodeles waltlii* embryos

	Stages	6 h		24 h	
		Normal (%)	Blocked (%)	Normal (%)	Blocked (%)
Fab'anti FN	Blastula (20)	20	80	20	80 (25)
	Early gastrula (16)	—	100	—	100 (18)
	Late gastrula (15)	80	20	80	20
Preimmune Fab'	Blastula (20)	100	—	100	—
	Early gastrula (25)	100	—	100	—
Fab'anti FN+FN	Blastula (25)	90	10	90	10
	Early gastrula (30)	93	7	93	7
BSA	Blastula (30)	100	—	100	—
	Early gastrula (15)	100	—	100	—
Steinberg solution	Blastula (12)	100	—	100	—
	Early gastrula (15)	100	—	100	—

Embryos were injected at three stages of development as described in the legend to Fig. 2 (number of treated embryos for each stage is given in parentheses); in all cases, monovalent antibodies and bovine serum albumin (BSA) were used at 20 mg ml^{-1}; the final concentration (4–10 mg ml^{-1}) in the blastocoel cavity cannot be estimated rigorously. With antibodies to fibronectin, the blastocoel roof of most embryos treated before or at an early stage of gastrulation developed into convoluted structures as in Fig. 2*f*. Partial necrosis was observed after 24 h in some embryos (percent indicated in parentheses) in which mesodermal cell migration did not occur.

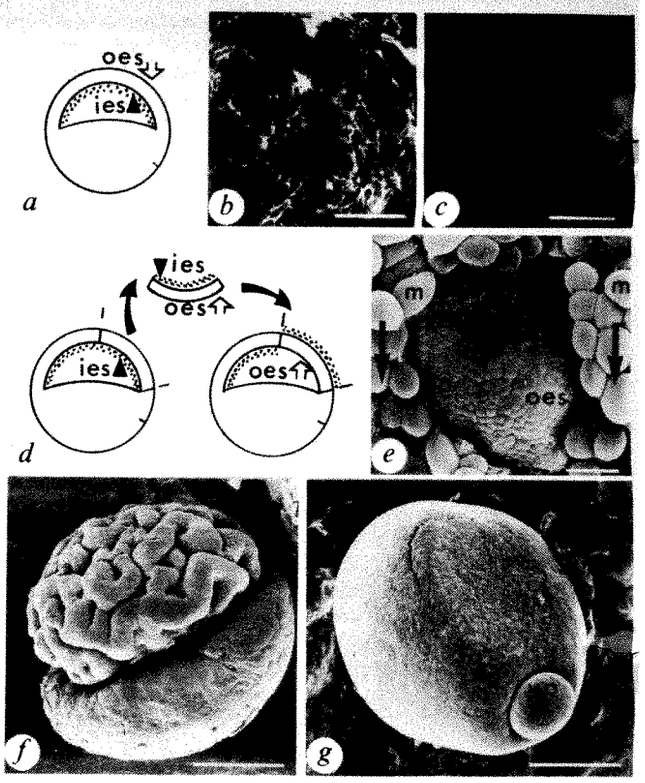

Fig. 2 Distribution and role of FN in *Pleurodeles waltlii* gastrulation. ***a–c***, Immunofluorescence labelling for FN: 4% formaldehyde-fixed or living ectoderm explants were incubated in anti-FN IgG (10 μg ml^{-1}) for 1 h followed by fluorescein isothiocyanate FITC-conjugated sheep anti-rabbit antibodies diluted 1:100 in 0.5% bovine serum albumin. Explants were whole-mounted in 90% glycerol, examined with epi-illumination through a Leitz Dialux 20 microscope and photographed with Kodak Tri-X films. *a*, Schematic representation of an early gastrula inner (filled triangle) and outer (open arrow) surface of the blastocoel roof. *b*, Staining for FN on the inner surface of the blastocoel roof. An extensive FN-rich fibrillar matrix covers the inner surface of the ectoderm layer. *c*, Unlike the inner surface, the outer surface of the blastocoel shows no fluorescence for FN. ***d, e***, Inverted explants were grafted to determine whether the FN-rich extracellular matrix mediates the migration of mesodermal cells. *d*, Schematic representation of the grafting procedure. An inverted ectodermal explant was grafted on the future dorsal side of the embryo above the blastoporal lip. The position of invaginated mesodermal cells was checked after gastrulation had progressed. *e*, Scanning electron micrographs of the blastocoel roof in a gastrula bisected 3 h after grafting. The mesodermal cells attach to the inner surface of ectodermal cells but do not adhere to the outer ectodermal surface of the graft. The overlapping cohesive sheet of mesodermal cells that follows the pioneer cells has been removed. It is clear that adhesion has not taken place between the migrating mesodermal cells and the outer surface of the ectodermal explant (arrows, direction of migration). ***f, g***, Injection of monovalent antibodies to FN into the blastocoel. 200 nl of a 20 mg ml^{-1} solution of Fab' anti-FN were injected into *Pleurodeles waltlii* blastulae or gastrulae. Similar amounts of preimmune Fab' or bovine serum albumin were injected as controls. Scanning electron micrographs were made 24 h after injection of blastulae. *f*, Gastrulation is almost completely inhibited when antibodies to FN are used; the blastocoel roof becomes folded extensively into disorganized convolutions. In contrast, the inner surface of the ectoderm remains smooth (not shown). The part of the embryo which should have invaginated is found as a cap. A very limited invagination can be observed at the boundary between the cap and the superficial ectoderm. This limited invagination can be visualized after removal of the ectoderm; however, mesodermal cells did not develop many filopodia and lamellipodia over the surface of the ectoderm and occupy only a very limited area as opposed to their homogeneous distribution over the entire surface of the ectoderm during normal development (not shown). *g*, Embryos injected with monovalent preimmune antibodies develop normally with only a small yolk plug (yp) at the site of invagination. For scanning electron microscopy, embryos or explants were fixed in 2.5% glutaraldehyde in 0.1 M cacodylate buffer, *p*H 7.4–7.6, at room temperature and postfixed in 1% OsO_4 in the same buffer. Samples were dehydrated through a graded ethanol series, critical point dried, coated with gold, examined with a Jeol JSM-35 scanning electron microscope at 25 kV and photographed with Ilford FP4 film. Scale bars: *b, c*, 20 μm; *e*, 100 μm; *f, g*, 320 μm. ies, Inner ectodermal surface; m, mesodermal cell; oes, outer ectodermal surface; yp, yolk plug.

24 h after injection of the same amount at the late gastrula stage. In control experiments, all the embryos reached the neurula stage when injected with preimmune monovalent antibodies, with Steinberg solution or with bovine serum albumin; in addition embryos cultivated in the presence of antibodies to FN develop normally (not shown). Most importantly, when antibodies to FN were preincubated with *Ambystoma mexicanum* FN, gastrulation proceeded normally (Table 1).

In gastrulating amphibian embryos, the presence of an extracellular matrix was suggested only recently[8,9]. Its early appearance was documented *in vivo* using scanning electron microscopy and a possible function as a guiding structure for migrating mesodermal cells was suggested[10]. Migration of amphibian mesodermal cells was also observed *in vitro* on the extracellular matrix transferred from ectoderm explants[11]. However, although it has been reported that FN mediates adhesion of mesodermal cells *in vitro*, it has not been shown so far that these cells utilize FN *in vivo* as a substrate for migration[12]. We have previously shown that FN is present at the blastula stage[7] and we establish here that it is a component of the fibrillar extracellular matrix within which mesodermal cells migrate.

The presence of the extracellular matrix could be required for attachment in grafting experiments (Fig. 2*d*); however, this experiment could merely indicate an ability of mesodermal cells to adhere only to basal surfaces. The importance of FN was clearly assessed by using specific monovalent antibodies to FN. Nevertheless we cannot exclude that other ECM components may also be essential for attachment and migration of mesodermal cells. It should be stressed that in itself FN does not trigger the process of invagination since it is already incorporated into the extracellular matrix prior to gastrulation. The early deposition of FN was also observed in chick embryos before gastrulation[13–15] and before neural crest cell emigration[16]. It is likely that mesodermal cells have an intrinsic ability to respond to the FN-rich matrix with which they interact directly. However, it is not clear whether the matrix fibrils are oriented in the direction of movement. Rather, confluency at all stages of migration may allow the cells to migrate unidirectionally as a result of population pressure, a mechanism also suggested by Kubota and Durston[17] for amphibians and by Rovasio *et al.*[5] for avian neural crest cells.

Once migration of mesodermal cells was almost complete, antibodies to FN did not perturb the formation of a neural plate. However, we cannot exclude that antibodies to FN introduced at the late gastrula stage had no effect since interactions between mesodermal and ectodermal cells leading to neurulation may not last more than several hours[18]. Nevertheless, the presence of a FN-rich extracellular matrix does not seem to be required, as a direct association of mesodermal cells with the outer surface of the ectoderm leads to neurulation[19].

The blood schizogonic cycle of human malaria parasites has thus far been the most exhaustively studied phase of parasite development. However, before entering red blood cells (RBCs), the parasite undergoes its first multiplication not in blood, but in hepatic cells. These hepatic stages were the last to be discovered[1] and only a few studies have been performed in humans and other primates[1–7]. Despite recent advances[8–11], *in vivo* studies have limitations and other approaches such as cultures of these liver forms may be necessary to investigate their chemosensitivity and their biochemical or immunological properties. Recently, sporozoites of species of rodent malaria have been made to infect cultured cell lines[12–15] or primary hepatocyte cultures[16–18]. We report here that the complete cycle of the human malaria parasite *Plasmodium vivax* can be obtained in primary cultures of human hepatocytes up to release of merozoites able to penetrate RBCs.

A new method for culturing metabolically active human hepatocytes using enzymatic perfusion has recently been described[19,20]. In the present experiment, we modified this method by canulating and perfusing a small blood vessel of a liver biopsy fragment obtained for diagnostic purposes. Preparation of hepatocyte monolayers and culture conditions are the same as previously described using rodent liver cells[17] except that the hepatocytes were seeded at a concentration of 5×10^5 cells per 35-mm Falcon Petri dish in 1.5 ml supplemented minimal essential medium. Such hepatocyte monolayers can easily survive for 1–2 weeks in conventional culture conditions or for several weeks with maintenance of high levels of specific functions when co-cultured with a rat liver epithelial cell line[20] (Fig. 1). In this experiment, since a liver biopsy fragment was obtained 2 days before availability of sporozoites, only four out of eight hepatocyte cultures were set up as co-cultures with epithelial cells (added at a concentration of 5×10^5 per dish) while the remaining four were set up as monocultures.

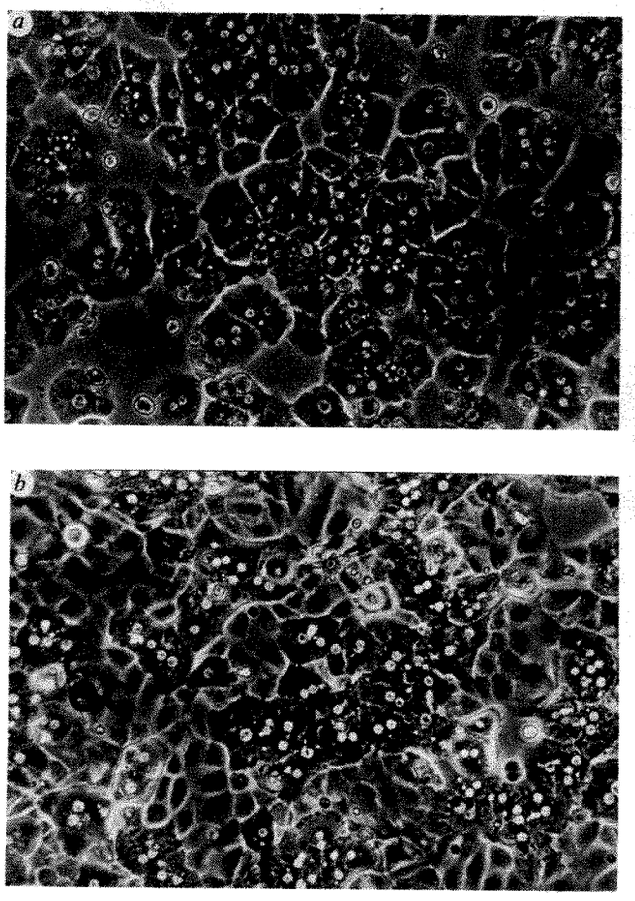

Fig. 1 *a*, Hepatocytes in monoculture (h). Note the flattened appearance of these cells. In monoculture, the hepatocytes will only remain fully functional for a short period (less than 2 weeks). *b*, Hepatocytes co-cultured with liver epithelial cells (ec). Hepatocytes appear more rounded and organized into cord-like groups. In these conditions the hepatocytes remain functional for up to 2 months. (×200.) Phase-contrast micrograph.

Sporozoites of *P. vivax* were obtained from *Anopheles stephensi* mosquitoes infected by membrane feeding with 10 ml of citrated blood containing gametocytes (5×10^7 ml^{-1}) collected from a patient who had been infected in India. Examination of mosquito midguts on day 11 following the blood meal showed that 15% of them were infected. On day 16, the mosquito salivary glands were aseptically dissected in culture medium. The culture supernatant from each Petri dish was decanted and groups of 10 pairs of salivary glands in 80 μl medium were added to each dish. The preparations were incubated for 45 min at 37 °C, with 5% CO_2 and 95% air after which 0.5 ml of medium was added, followed by an additional 1 ml 5 h later. Subsequently, the medium was changed daily. In one culture fixed on day 5 following sporozoite inoculation and stained with Giemsa, an exo-erythrocytic schizont of small size (10 μm) was identified. In two of three monocultures fixed on day 7 of culture, intracellular schizonts of various sizes were seen (Fig. 2*a–d*), but only a few were observed in the third culture. The larger ones measured 30 μm and contained up to 200–300 nuclei. Smaller schizonts ranged from 10 to 25 μm. The smallest was 5 μm and contained five nuclei. They were generally located close to the nucleus of the host cell which appeared unaltered by the presence of the schizont except for a condensed area surrounding a clear space around the schizont. Schizonts could be seen over the entire area of the culture but were more numerous in the vicinity of the introduced salivary glands. The number of schizonts seen was relatively high (about 30 in each of two dishes).

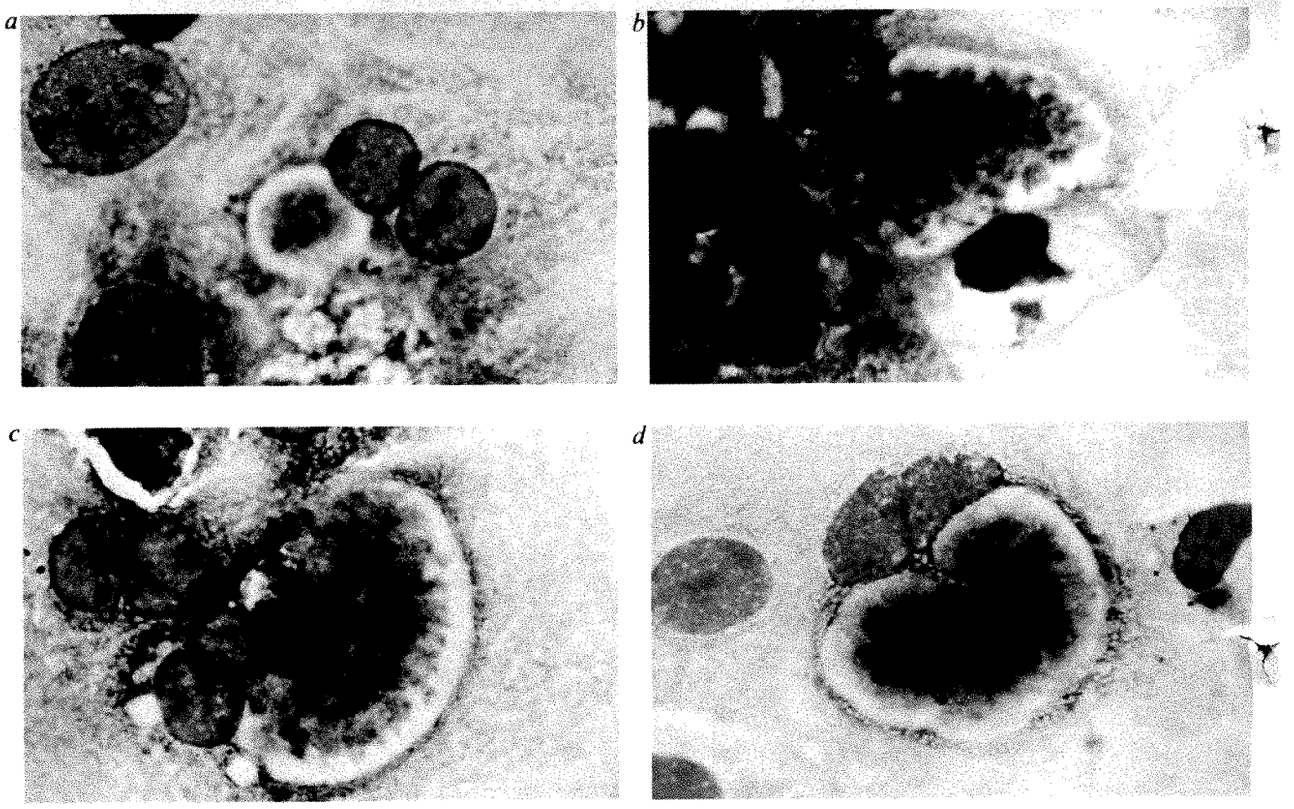

Fig. 2 Seven-day exo-erythrocytic parasites of *P. vivax* in cultural hepatocytes (×1,300). *a*, Early schizont with only a small number of nuclei. *b*, Maturing schizont with a greater number of nuclei. *c*, *d*, Late schizont undergoing segmentation. Giemsa staining.

To establish unequivocally whether the hepatic schizonts could achieve full maturity *in vitro*, we added RBCs to two hepatocyte co-culture dishes on day 10. Because *P. vivax* preferentially penetrates young RBCs, blood collected from a patient with a 30% reticulocytosis was used. Following two washes in culture medium, this blood was added at a concentration of 10^8 blood cells per culture dish. Thin blood films were made on days 12 and 14. Numerous intra-erythrocytic *P. vivax* parasites were identified on both preparations after staining with Giemsa. Most of the intra-erythrocytic forms were rings, although some were trophozoites containing malarial pigment, and one schizont with eight nuclei was seen. Schüffner's dots were present in many of the infected cells. In the hepatocytes of this latter culture dish fixed on day 14 no intra-hepatocytic parasite could be unequivocally identified.

No uninucleated body of recognizable parasite origin was seen in any of the dishes fixed on days 5, 7 and 14. However, we emphasized that the uninucleated liver forms of *P. vivax* known as hypnozoites, which have been described recently in the liver of infected chimpanzees[8], might be difficult to find on Giemsa-stained preparations because of their size. Unfortunately the small number of cultures infected in these experiments did not allow us to perform other more specific staining procedures, for example, using labelled antibodies.

It was further shown that the cultured hepatocytes had retained their differentiated functions throughout the experimental period by measuring their ability to produce albumin. Human albumin levels in culture supernatant, as measured by an immunonephelometric method, varied from 2.7 to 4 $\mu g\ ml^{-1}$ from day 1 to day 11.

These results demonstrate that the full pre-erythrocytic cycle of *P. vivax* can be completed *in vitro*, using the methods described. It is now important to determine, first, if a human cell is required and, second, if an hepatocyte must be fully differentiated and functional to support penetration of sporozoites and complete exo-erythrocytic development up to the point of infective merozoite release. Doby and Barker[21] observed a small number of intra-cytoplasmic bodies (11–21 μm) following inoculation of *P. vivax* sporozoites into a human liver cell culture which had been maintained *in vitro* for at least 1 month before the addition of the sporozoites. Beaudoin and Hollingdale recently reported that *Plasmodium falciparum* and *P. vivax* sporozoites entered cells of a human lung embryonic line (WI38) as well as a hepatoma line (Hep G_2-A_{16}), but that development was not observed[22]. It is noteworthy that in these previous studies the cells were never fully functional hepatocytes and in no case was complete exoerythrocytic development observed.

These results suggest that, although human malaria parasites may infect a variety of cell types, only the functionally intact hepatocyte may provide the proper conditions for complete exo-erythrocytic development of *P. vivax*. On the other hand, more extensive experiments performed using species of rodent malaria have clearly shown that the specificity for the host cell may not be exclusive[15–18]. Furthermore, indications gained from *in vivo* studies suggest that the species specificity of the liver forms of human plasmodium may not be as restrictive as for the erythrocytic stages[9].

One area of considerable interest associated with the cultivation of exo-erythrocytic stages of *P. vivax* could be to provide a new approach to evaluating the merit of the alternative hypothesis on the nature of the secondary exo-erythrocytic cycle, that is, a dormant uninucleated form called hypnozoite, as against a continuing intrahepatic schizogonic cycle.

As *in vitro* cultivation of the erythrocytic stages of malaria has led to major advances in our knowledge of these stages[23], the *in vitro* culture of the liver stages could also open up a wide range of applications. These are limited at present in part by the supply of sporozoites and of human hepatocytes. It is still necessary, therefore, to try to adapt the system to continuous cell lines. However, even if schizont development in other cell types is shown to be possible, it may well be found ultimately

that a homologous, functional hepatocyte is the cell of choice for certain applications, that is, chemotherapeutic studies which would be best performed using the cell type involved in the metabolism of the drugs being examined.

Endogenous ouabain-like compound increases heart muscle contractility

Yakhin Shimoni, Mervyn Gotsman, Joseph Deutsch*, Silvia Kachalsky & David Lichtstein

Department of Physiology and *Department of Pharmaceutical Chemistry, Hebrew University Hadassah Medical School, Jerusalem, Israel

Cardiac glycosides such as digoxin or ouabain have long been known to influence the strength of contraction of cardiac muscle[1–3]. Although the mechanism of action of these compounds remains unknown[4,5], all the proposed modes of action are based on initial binding to specific membrane receptors which are part of the $(Na^+ + K^+)$ATPase complex. These receptors, well characterized and defined[6–8], suggest the existence of an endogenous substance capable of binding to them, in analogy with endogenous opiates, discovered long after morphine and its receptors[9]. As glycosides affect $(Na^+ + K^+)$ATPase activity, an endogenous substance may be a regulator of this important enzyme. Indeed, the search for endogenous regulators of the $(Na^+ + K^+)$ATPase or ouabain-like compounds (OLC) has recently intensified. These compounds, extracted and partially purified from mammalian brain[10–14], heart[15], blood[16–19] and urine[20,21], and from toad skin and plasma[22,23], have been shown to inhibit ^{3}H-ouabain binding and $(Na^+ + K^+)$ATPase activity. We report here that in addition to these effects, the OLC, highly purified from toad skin and sheep brain, increases the force of contraction of frog and guinea pig atrium.

The toad skin OLC was extracted from 50 g of back and abdominal toad skin (*Bufo viridis*) into 500 ml methanol. The methanol was filtered and evaporated and the residue redissolved in 20 ml distilled water. Material which was not dissolved was precipitated by high speed centrifugation (100,000*g*). The supernatant was separated and lyophilized. The residue was dissolved in a minimal volume of methanol (~1 ml) and 20–100-μl aliquots were injected on HPLC. The chromatographic pattern of the separation is shown in Fig. 1*a*. The main peak with biological activity (that is, inhibits ^{3}H-ouabain binding and $(Na^+ + K^+)$ATPase activity, see below) was obtained at a retention time of 28 min. This peak was collected and rechromatographed on the same system, and the separation is shown in Fig. 1*b*. The material from the peak at 28 min (second separation) was collected and used in the physiological experiments.

The sheep brain OLC was extracted from brain tissue by acidified acetone and separated on a Sephadex G-25 column as previously described[12,13]. The biologically active peak obtained from the Sephadex column was further separated on the HPLC column described above (for the toad skin OLC).

Figure 1*c* shows that the material separated at a retention time of 28 min from toad skin is capable of inhibiting ^{3}H-ouabain binding to synaptosomes prepared from rat brain. The inhibition is dose dependent with half-maximal inhibition at 100 μg of wet weight of skin per ml. By comparing this activity with ouabain (Fig. 1*c*), and assuming that ouabain and OLC have the same affinity towards their mutual binding site, the concentration of OLC in the skin was calculated to be approximately 0.6 nmol per g tissue, was used to calculate OLC concentrations in the following experiments. The OLC separated at 28 min also inhibited $(Na^+ + K^+)$ATPase activity in the rat brain microsomal fraction, but had no effect on Mg^{2+}-ATPase activity (data not shown). These findings confirm previous reports on the presence of ouabain-like compounds in this tissue[22,23]. Interestingly, the endogenous OLC compound is capable of inhibiting $(Na^+ + K^+)$ATPase activity only at concentrations 100-fold higher than those required to inhibit ouabain binding.

Tension recordings were done from frog atrial trabeculae, placed in a 2-ml chamber and perfused with a normal Ringer solution (for composition see Fig. 2 legend). One end was attached to an AKERS force transducer for measuring the strength of contraction. Constant stimulation was applied at a rate of 0.5 Hz and twitch magnitude was monitored on a pen recorder and oscilloscope and stored on magnetic tape.

Addition of the endogenous, partially purified OLC from toad skin resulted in a marked increase in the force of contraction. This increase was dose dependent and reversible on washout. A positive inotropic effect was sometimes seen at as low a dose as 5×10^{-8} M, but more commonly doses of 10^{-7} M and higher gave significant positive inotropy. An example is shown in Fig. 2*a*. This effect was seen in seven out of seven cases. The amount of positive inotropy, however, was quite variable in the individual experiments, as indeed is the case with the cardiac glycosides themselves[24]. A partial dose–response curve was obtained, limited by the quantity of purified compound. Figure 2*b* illustrates the larger effect produced by the higher doses. No saturation was observed in this limited range. It should be emphasized that, as mentioned above, the concentrations are all calculated from the binding experiments and the true concentrations may actually be different. In one case (Fig. 2*c*) a high dose of 6 μM produced toxic effects, similar to those obtained with high doses of ouabain[25]—an increase in the basal (tonic) tension and a reduction in the phasic (twitch) tension.

Several reports suggest that cardiac glycosides exert their inotropic effect by activating the release of endogenous stores of catecholamines[25–27]. Since our effect was obtained with incompletely identified compounds, we repeated the experiments in the presence of adrenergic blockers. As both α- and β-receptors have been found in several cardiac preparations, including the frog atrium[28–30], we used a combination of phentolamine and propranolol, respectively α- and β-blockers. In 10 out of 14 cases, the OLC caused a marked positive inotropic effect in the presence of concentrations between 10^{-6} and 5×10^{-6} g ml^{-1} of both blockers (Fig. 2*d*). As both blockers alone

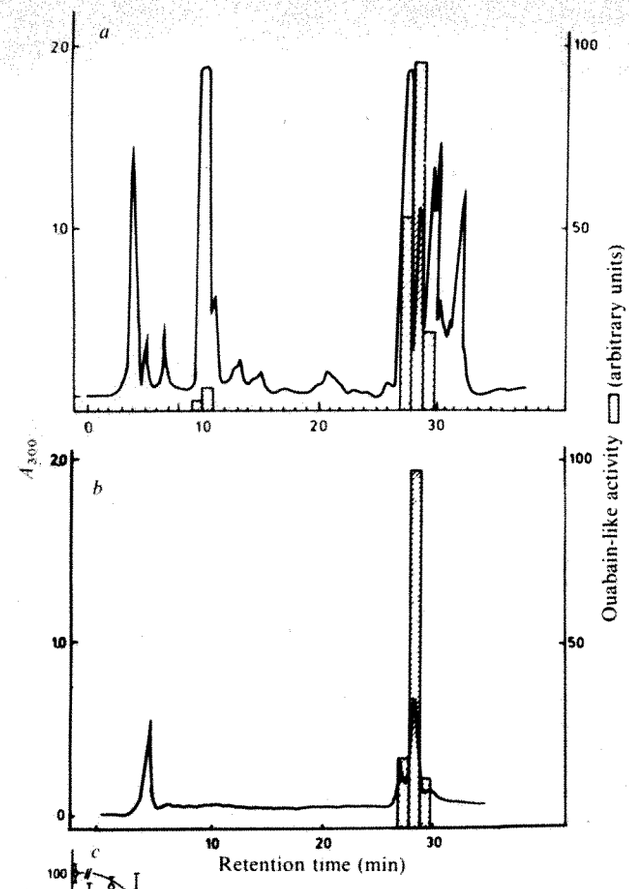

Fig. 1 *a*, *b*, HPLC of the toad skin OLC and its biological activity. The optical density is plotted (left ordinate) against retention time (abscissa). The right-hand ordinate is the relative biological activity, shown as hatched columns in the graph. This activity was measured by testing the capability of each fraction to inhibit both ^{3}H-ouabain binding and $(Na^+ + K^+)$ATPase activity. *c*, Inhibition of ^{3}H-ouabain binding to rat brain synaptosomes by toad skin extract. The inhibition of binding at different concentrations of ouabain (○) or OLC (●) are shown. The OLC was from samples taken at peak retention time of 28 min.

Methods: *a*, Methanol extract of toad skin (*Bufo viridis*) corresponding to 50 g of skin was dissolved in 1 ml methanol. A Tracor 985 HPLC instrument was used. Aliquots of 20–100 µl were applied to a Alltech amino column (4.6×250 mm, 10 µm particle size), equilibrated with 90% acetonitrile. The column was eluted with linear 90–70% acetonitrile gradient in 40 min, at a flow rate of 1 ml min^{-1}. The elution of the compounds was monitored at 300 nm, using a Tracor 970 A UV detector. Fractions of 1 ml were collected, evaporated and the residue was dissolved in 1 ml distilled water. 50-µl samples from this solution were used for measurements of biological activity (*c*). *b*, Fractions (1 ml) with a retention time of 28 min collected from the chromatography in *a* were evaporated to dryness and dissolved in 0.5 ml methanol. Aliquots of 20 µl were applied to the same HPLC system described above. The fractions with a retention time of 28 min were collected, evaporated to dryness and stored at −20 °C for 1–6 weeks. These samples were used in the physiological experiments described in Figs 2 and 3. *c*, The methods for synaptosome preparation have been described elsewhere[12]. ^{3}H-ouabain binding was determined by incubating about 0.2 mg synaptosomal protein in 0.5 ml medium, containing (in mM): Tris-HCl buffer (*p*H 7.4) 50, EDTA 0.5, NaCl 80, $MgSO_4$ 4, ATP 2 (Tris, vanadium-free), 32 nM ^{3}H-ouabain (NEN, 19.5 Ci mmol^{-1}), with or without toad skin extract. Following incubation for 60 min at 37 °C, at which time a binding equilibrium is achieved, the reactions were terminated by the addition of 3 ml of cold 50 mM Tris-HCl (*p*H 7.4), and filtration over Whatman GF/B filters. Filters were washed twice with 3 ml of the same Tris buffer, dried and assayed for radioactivity in a Packard liquid scintillation counter at counting efficiency of ~35%. Specific binding was calculated by subtracting the binding observed in the presence of 100 µM unlabelled ouabain. Specific binding represented 93% of the total binding in control conditions. The control binding in the absence of extract or unlabelled ouabain was 12.5 pmol ^{3}H-ouabain per mg protein, and was taken as 100%.

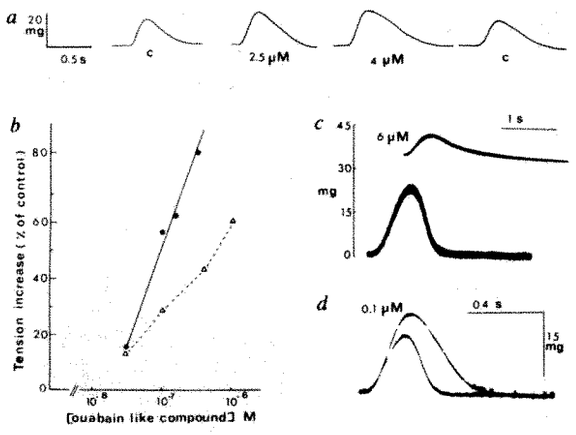

Fig. 2 *a*, The positive inotropic effect of the toad skin OLC on frog atrium. Pen recorder tracings, obtained from frog atrial trabeculae (4–6 mm long, 200–400 µm diameter), during constant 0.5-Hz stimulation. From left to right are the responses in control(c) Ringer, following addition of 2.5 µM OLC, 4 µM OLC and following 20 min washout (c). Control Ringer solution contained (in mM): NaCl 90, $NaHCO_3$ 20, KCl 2, $CaCl_2$ 1.1, $MgCl_2$ 1.0, Na_2HPO_4 0.4, glucose 5.5, bubbled with a 95–5% O_2–CO_2 mixture. The *p*H was 7.6–7.7 and the temperature 21–24 °C. Longer washouts gave more complete reversal of the positive inotropic effect. *b*, A partial dose–response curve. In two cases, four concentrations of OLC were tested. The plot gives the tension increase versus dose (see text for discussion of concentrations of OLC and their estimation). The doses were given cumulatively, with steady state being attained at each dose, before addition of the higher dose. In other experiments two or three doses were used, giving larger effects at higher doses. *c*, A toxic effect of OLC. At a higher concentration (6 µM in this single case) toxic manifestations developed, similar to those obtained with high ouabain levels. The plot shows the elevation in baseline tension as well as the reduced twitch, in the presence of 6 µM OLC, as compared with the control twitch. *d*, The effect of OLC in the presence of α- and β-blockers. Two superimposed oscilloscope records of tension: in a 'control'Ringer solution, containing also 5×10^{-6} g ml^{-1} phentolamine and propranolol (smaller twitch), and after the addition of 0.1 µM OLC(larger twitch).

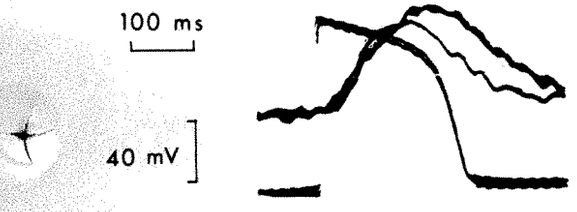

Fig. 3 The positive inotropic effect of sheep brain OLC on sheep heart. OLC was extracted from seven sheep brains by acidified acetone, and partially separated by Sephadex G-25 chromatography, as previously described[12,13]. The active material obtained from this separation was further purified using the HPLC system described in Fig. 1*a* legend. The OLC concentration was estimated by comparing its ability to displace ^{3}H-ouabain binding to rat synaptosomal membranes. The upper tracings show the superposition of tension traces obtained from a sheep ventricular trabeculum. The smaller tension is in a control solution (containing, in mM: NaCl 140, KCl 5.4, $NaHCO_3$ 12, CaCl 2, $MgCl_2$ 1, Na_2HPO_4 0.4, glucose 5, continuously bubbled with 95–5% O_2–CO_2, with a *p*H of 7.4 at 36 °C). The larger tension response was obtained following the addition of 5×10^{-8} M sheep brain OLC. The positive inotropy was fully reversed on washout. The vertical bar equals 20 mg, as well as 40 mV. The lower traces show the superimposed action potentials, recorded with an intracellular, 3 M KCl microelectrode. There was no significant change in resting potential or in the action potential configuration, aside from a possible small elevation in the plateau phase.

have negative inotropic effects, the two cases without effect and the two in which a negative inotropic effect was produced were attributed to persistent, delayed blocker action.

We next tested this compound on a mammalian preparation to investigate a possible more general applicability. In three experiments on atrial trabeculae from guinea pig hearts, the OLC gave a large positive inotropic response (data not shown). In one case, the same effect was produced in the presence of 5×10^{-6} g ml^{-1} α- and β-blockers.

Brain OLC was previously shown to bind to ouabain receptors and to inhibit $(Na^+ + K^+)$ATPase activity[10–14]. In a single trial (Fig. 3), it produced a reversible positive inotropic effect on a trabeculum from sheep ventricle. This 22% increase in contractile force was accompanied by very little change in the action potential configuration, as measured by an intracellular microelectrode.

The chemical nature of the OLC is obviously of major importance. Partial characterization using Sephadex columns and sensitivity to proteolytic enzymes (data not shown) reveals that the toad skin and brain OLCs are of low molecular weight (<500) and are not peptides. It is well known that the toad skin contains toxins which are capable of inhibiting $(Na^+ + K^+)$ATPase, the bufodienolide toxins[31]. It is therefore possible that the OLC separated by us are these steroidal toxins. Experimental results, however, do not favour this possibility: (1) The retention time on the HPLC system described above is in the range of 5–10 min for steroidal compounds (such as ouabain itself), which does not correspond to the main peak of activity found (retention time of 28 min). (2) Only ~5% of the biological activity present in the 28-min peak (aqueous solution) partitioned into 10 volumes of chloroform or ether, indicating that the active principle is relatively polar, unlike the bufodienolides. (3) The UV spectrum of bufodienolides shows a peak at 300 nm, while the spectrum of the compound separated by us shows a maximum at 278 nm and a shoulder at 300 nm (data not shown).

In conclusion, we have shown that the endogenous OLCs extracted from toad skin and mammalian brain are capable of increasing the force of cardiac muscle contraction. This raises the possibility that they serve as physiological regulators of cardiac function. Clearly, further investigation is needed.

β-Adrenergic modulation of calcium channels in frog ventricular heart cells

Bruce P. Bean*, Martha C. Nowycky & Richard W. Tsien

Departments of Physiology and Neuroanatomy, Yale University School of Medicine, New Haven, Connecticut 06510, USA

Adrenergic modulation of calcium channels profoundly influences cardiac function[1,2], and has served as a prime example of neurohormonal regulation of voltage-gated ion channels[1–7]. Channel modulation and increased Ca influx[2,8,9] are mediated by elevation of intracellular cyclic AMP[10–17] and protein phosphorylation[18,19]. The molecular mechanism of the augmented membrane Ca conductance has attracted considerable interest. An increase in the density of functional channels has often been proposed[20–22], but there has previously been no direct evidence. Single-channel recordings show that isoprenaline or 8-bromocyclic AMP increase the proportion of time individual channels spend open by prolonging openings and shortening the closed periods between openings[2,23–25]. To look for an additional contribution of changes in the number of functional channels, we applied ensemble fluctuation analysis[26] to whole-cell recordings[27,28] of cardiac Ca channel activity. Here we present evidence that in frog ventricular heart cells β-adrenergic stimulation increases N_F, the average number of functional Ca channels per cell. We also find that isoprenaline slows the time course of both activation and inactivation, and that the enhancement of peak current decreases gradually with greater membrane depolarization.

Frog ventricular cells were chosen because they have a robust β-adrenergic response[8,22]. We used barium as the current carrier instead of Ca to avoid possible contamination from Ca-activated potassium channels, to block currents through background K channels[29] and to improve resolution of the fluctuation analysis by increasing the single-channel current. Series-resistance compensation was used (Fig. 1 legend) and linear leak and capacity

currents were subtracted to give the traces shown. All experiments were carried out at room temperature (22 °C).

The β-adrenergic agonist isoprenaline strongly enhanced Ca channel current carried by Ba ions (Fig. 1). Figure 1*a* shows whole-cell currents recorded during depolarizing voltage-clamp pulses from −60 mV to +10 mV. Ca channel current increased from about 0.7 nA in the absence of drug, to about 3.5 nA in the presence of isoprenaline: the effect was fully reversed following washout of the drug. Figure 1*b* illustrates the time course of the response and the stability of the current amplitude. The increase of Ca channel current was fairly typical; in 25 cells exposed to 0.5 μM isoprenaline, the whole-cell current increased by a factor of 6.2 ± 0.6 (mean ± s.e.m.), with individual increases as large as 15-fold.

The current carried by Ca channels (I) depends on three factors: the number of functional channels (N_F), the probability that an individual channel is open (p), and the current carried by an open channel (i). Which of these factors changes with β-adrenergic modulation? To answer this question, we applied ensemble fluctuation analysis as developed by Sigworth[26]. Ensembles of successively evoked current transients were collected, aligned in time and analysed for the time course of the mean current and the time course of the variance associated with differences in channel activity from one record to the next. Mean and variance records from control and isoprenaline runs are illustrated in Fig. 2*a,b*. Both the mean current and the variance rose to maximum levels at the end of the depolarizing pulse; like the mean current, the variance increased about fivefold after exposure to isoprenaline. To estimate N_F, p and i for each run, plots of the variance versus mean current (Fig. 2*b,c*) were fitted by parabolic curves given by $\text{var} = iI - I^2/N_F$. This is the relationship expected for N_F identical, independent, functional channels having one non-zero current level i (ref. 25). The values for N_F and i were obtained by a least-squares curve-fitting procedure. The maximal probability p_{max} was then calculated as $p_{max} = I_{max}/(N_F i)$.

In the experiment shown in Fig. 2, N_F increased from ~11,000 to ~37,000 with isoprenaline. The maximal probability increased from 0.40 to 0.58 while the unitary current i remained unchanged at about 0.15 pA. These findings were representative of collected results from a total of eight frog ventricular cells (Table 1). The average value of N_F increased about threefold, while p_{max} increased by about 50%. After recovery from the isoprenaline effect, fluctuation analysis was more difficult because of Ca channel rundown and sweep-to-sweep shifts in baseline. Nevertheless, results from three cells suggested that N_F returned to its pre-isoprenaline level.

One of the most important assumptions of the fluctuation analysis is that the functional channels behave as a single, homogeneous population. Although this is untested, all of our observations seem consistent with this view. When frog ventricular cells are studied with long depolarizing pulses, the Ba current decays as a single exponential over a broad range of potentials. When fluctuation analysis is done on the falling phase of current in these ionic conditions, variance-mean plots are well fitted by a single parabola, with p_{max} near 0.4, just as in analysis of the rising phase in Fig. 2*b*.

This is the first evidence that the number of functional calcium channels is enhanced by β-adrenergic stimulation, as proposed by Reuter and Scholz[21] and by others[20,22]. At the membrane potential level studied here (+10 mV), the overall enhancement of Ca channel current is dominated by the increase in N_F. At other potentials other factors may have a more important role, as discussed below.

Is the Ca channel current simply scaled by β-adrenergic stimulation, or are there changes in time or voltage dependence? Whole-cell recordings allow the kinetics to be studied with good time resolution over a broad range of potentials. Figure 3*a* shows that the enhancement of inward Ba current in frog ventricular cells is accompanied by a clear slowing in the time course of activation (see also Figs 2*a*, 4*a*). The slowing is obvious when the control record is scaled up to match the isoprenaline-enhanced trace (lower part of Fig. 3*a*). The isoprenaline-induced slowing seemed little changed when $[Ba]_0$ was varied between 1 and 30 mM or when membrane potential was varied between −35 and +25 mV. Most of the analysis was done at +10 mV in 10 mM $[Ba]_0$. When the onset of inward current was fitted by a single exponential with a delay (a good approximation for all but the first millisecond after the step), the exponential time constant increased with isoprenaline in 13 out of 13 frog ventricular cells. The time constant was 1.58 ± 0.08 ms (mean ± s.e.m.) in control preparations and 2.47 ± 0.08 ms in isoprenaline-exposed preparations. Neonatal rat ventricular cells show a similar slowing during exposure to isoprenaline (Fig. 4*b*), although the enhancement of peak inward current was at most twofold, and typically much less.

Figure 4*a* compares the peak current–voltage relationship before and after β-adrenergic stimulation, and Fig. 4*b* plots the

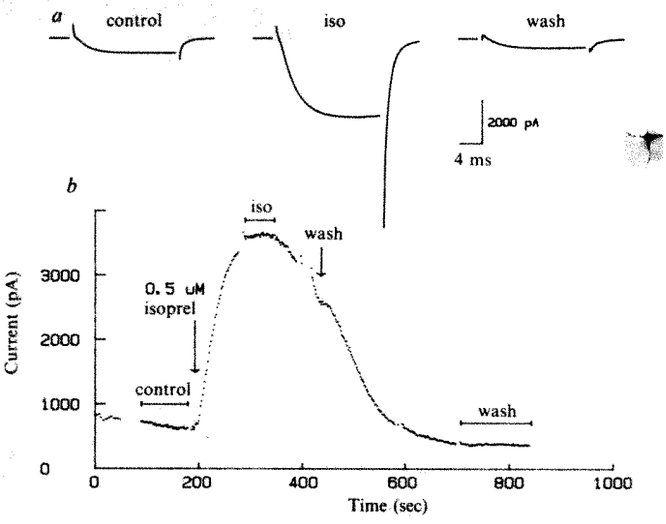

Fig. 1 Increase of Ba currents by isoprenaline. *a*, Currents elicited by a voltage step to +10 mV from a holding potential of −60 mV. Tail currents evoked by a repolarization to −40 mV. Leak and capacity currents (obtained from mirror-image hyperpolarizing pulses, 10 times smaller) have been subtracted, and a 750-μs period is blanked due to amplifier saturation during capacity transients. Each current shown is the mean current of the series of pulses indicated in *b*. *b*, Time course of isoprenaline response. Current measured at the end of the 20-ms test pulse. 200 μl of isoprenaline stock solution was squirted into the 1.5-ml chamber to give a final concentration of 0.5 μM. During the wash, the chamber volume was replaced 20 times with agonist-free solution within the first minute. Note that the current amplitude began to fall before the drug was washed out; in other experiments, current fell back to a stable value near its original level in 5–10 min even though the drug was not washed out, suggesting desensitization or depletion of some intracellular constituent. Cell F04B. Total capacity 75 pF. Series-resistance compensation for 2.2 MΩ out of a measured series resistance of 3.5–3.8 MΩ.

Methods: Single ventricular cells were isolated from bullfrog (*Rana catesbiana*) hearts following the procedure described by Hume and Giles[34] for atrial cells (see also ref. 35). Our procedure included some modifications. After 2–3 h in the final 0.05% collagenase solution, the pieces of ventricle were triturated using a Pasteur pipette. After another 2–3 h of digestion, the cell-containing collagenase solution was diluted 1:4 with (in mM) 1 $CaCl_2$, 160 NaCl, 5 KCl, 1 $MgCl_2$, 10 glucose, 5 HEPES *p*H 7.6. Cells were used 2–24 h after being isolated. For recording whole-cell voltage-clamp currents[7,28], cells were placed in solution containing (in mM) 10 $CaCl_2$, 130 NaCl, 5 KCl, 1 $MgCl_2$, 10 glucose, 5 HEPES *p*H 7.6. Electrodes (1–3 MΩ) contained (in mM) 120 CsCl, 10 Cs-EGTA, 5 $MgCl_2$, 10 HEPES *p*H 7.5. After formation of a gigaseal and rupture of the cell mumbrane, the external solution was changed to (in mM) 10 $BaCl_2$, 135 TEA-Cl, 1 $MgCl_2$, 10 glucose, 10 HEPES *p*H 7.65. Pipette series-resistance (measured as the time constant of the uncompensated capacity transient divided by the cell capacity) was 2–8 MΩ, of which 60–80% was compensated.

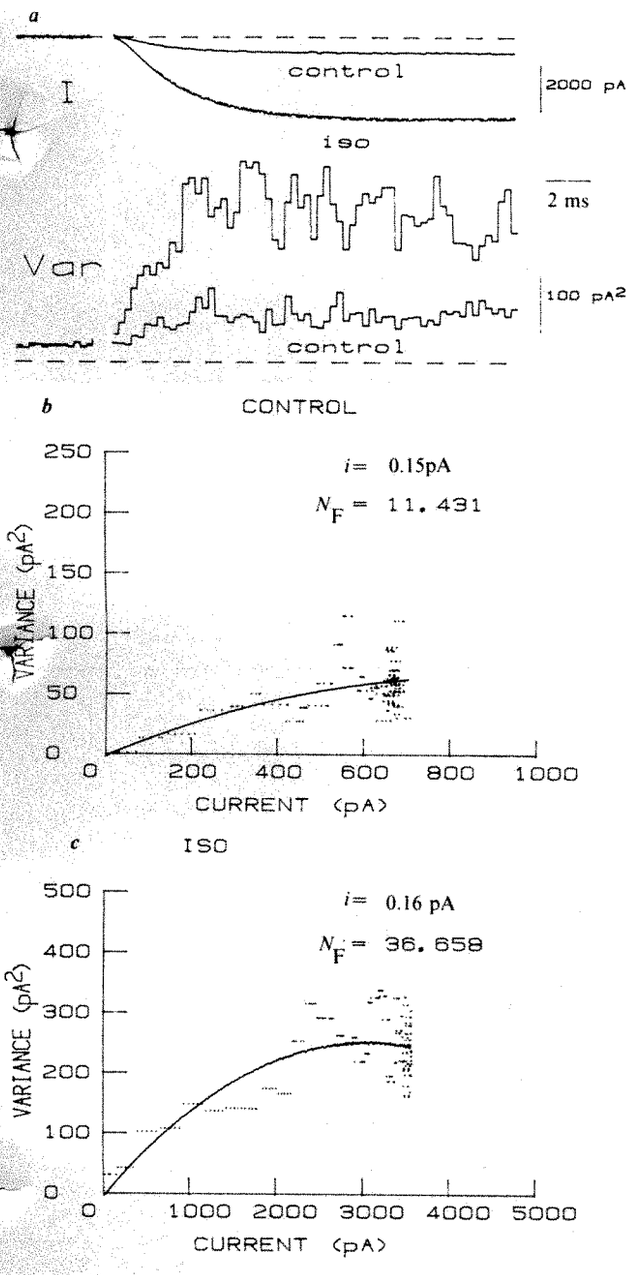

Fig. 2 Fluctuation analysis of Ca channel currents. Same experiment as Fig. 1. Ensembles of currents were elicited by a series of identical pulses to +10 mV (46 in the control and 31 with isoprenaline). Currents were sampled at 30-μs intervals after being filtered at 3 kHz (4-pole Bessel). Mean current and variance were computed for each time point. To minimize errors from slow drifts in current size, variance was calculated from successive pairs of records and averaged over the pairs; also, the first record of each pair was first scaled by a constant factor to allow for very slow rundown. The first millisecond of the test pulse was omitted from the analysis because the current showed an outward bump during this time; the variance was approximately at its background level. *a*, Mean and variance as a function of time. Mean currents corrected for capacity and leak current. The variance was averaged over 10 successive time points. Dotted lines indicate zero levels. *b*, *c*, Variance plotted against mean current. The background variance (computed from the current at the holding potential) was first subtracted from the variance during the test current.

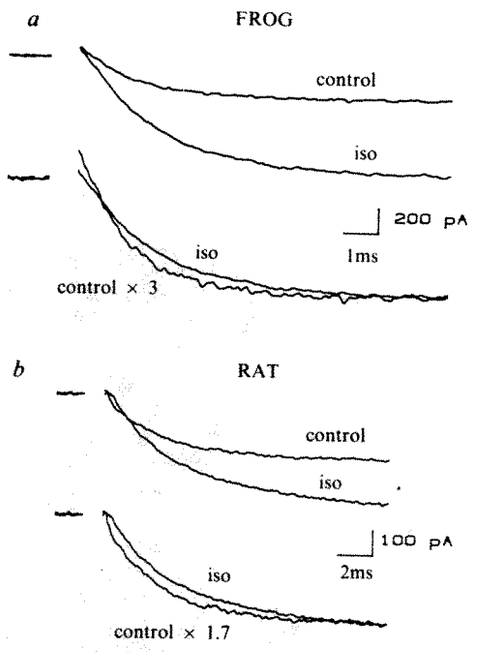

Fig. 3 Effect of isoprenaline on the time course of Ca channel activation. Recordings are shown at orginal amplification (upper traces in each panel), and with control record scaled up to the same magnitude as the isoprenaline trace (lower traces in each panel). *a*, Frog ventricular cell, 10 mM Ba external solution. Currents evoked by a step depolarization from −60 to +10 mV. Cell F06I. *b*, Cultured rat ventricular cell, 10 mM Ba external solution as in *a*. Currents elicited by a depolarizing step from −60 to +30 mV. Cells were cultured from 1–3-day-old rat hearts[36]. The recordings shown here were made on day 3 after culture. Cell M80I.

ratio I(iso)/I(control) as a function of potential. The enhancement of Ca channel current falls from about 11-fold at −40 mV to slightly more than 4-fold at +10 mV (close to the 6-fold average value mentioned earlier). The ratio continues to decrease as the test potential approaches and exceeds the reversal potential for Ca channel current (near +50 mV in the control run). At strongly positive potentials, isoprenaline increases the outward current very little.

The voltage dependence cannot be accounted for by errors due to the series resistance of the pipette or the longitudinal resistance of the cell (see Fig. 4 legend). Interference from other ionic channels would also appear unlikely, in view of the ionic conditions (external Ba and tetraethylammonium (TEA), internal Cs and EGTA), and experiments using the Ca channel blocking drug verapamil (Fig. 4*c–e*). Verapamil totally abolishes the isoprenaline-enhanced current, whether it is inward (0 mV, Fig. 4*c*) or outward (+120 mV, Fig. 4*e*). At the reversal potential in the control run (+50 mV, Fig. 4*d*), the net driving force for Ca channel current is zero and as expected, neither isoprenaline[21] nor verapamil[30] has any effect. This experiment leaves little doubt that the outward current reflects Ca channel activity alone. Thus, it is notable that β-stimulation hardly increases the peak outward current at all (Fig. 4*a*,*e*).

The main effect of isoprenaline in Fig. 4*e* is a marked slowing of the decay of the outward current. Slowing of inactivation is also manifested by the decay of inward currents accompanying less positive test depolarizations (data not shown), and by the behaviour of inward tail currents evoked by sudden repolarization after test pulses of varying duration, studied in another cell (Fig. 4*f*,*g*). In a control run (Fig. 4*f*), the amplitude of tail currents decreases gradually along with outward current inactivation; after exposure to isoprenaline (Fig. 4*g*), the amplitude of tails is maintained, like the outward current.

Outward current and tail current appear not to vary concomitantly in their response to isoprenaline: inward tail currents seem to be strongly enhanced at a time (vertical arrow) when

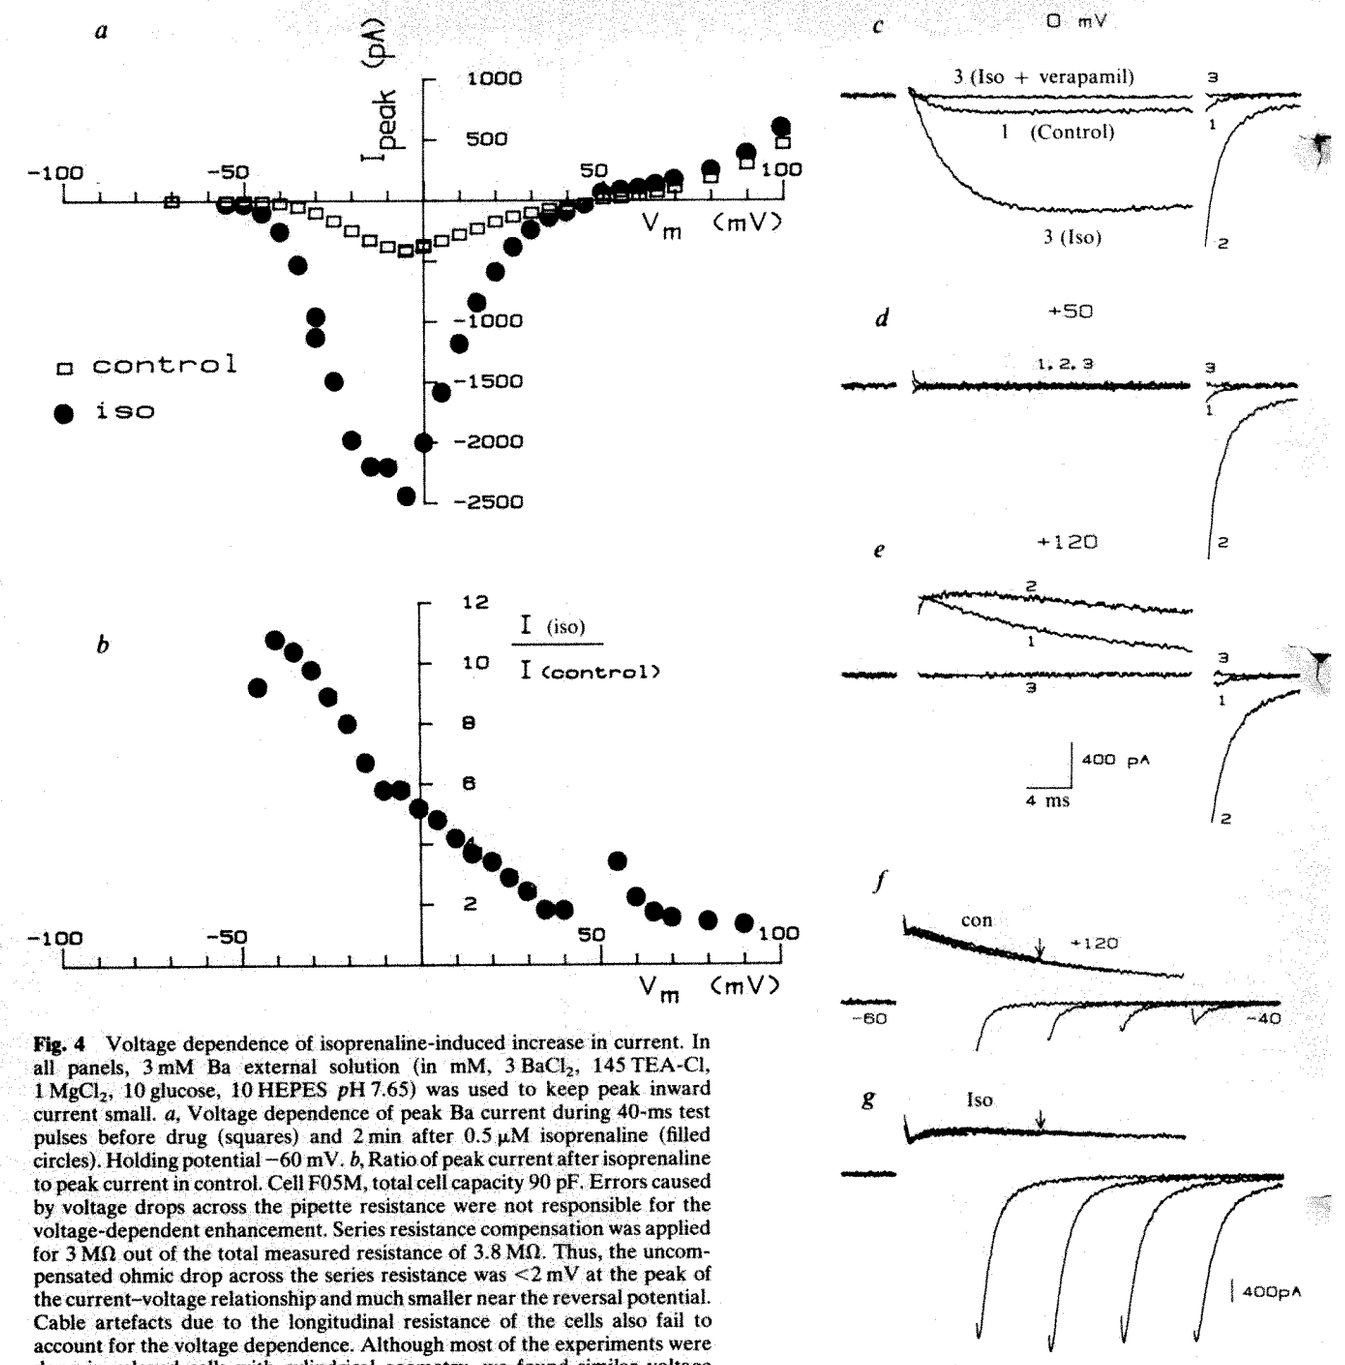

Fig. 4 Voltage dependence of isoprenaline-induced increase in current. In all panels, 3 mM Ba external solution (in mM, 3 $BaCl_2$, 145 TEA-Cl, 1 $MgCl_2$, 10 glucose, 10 HEPES *p*H 7.65) was used to keep peak inward current small. *a*, Voltage dependence of peak Ba current during 40-ms test pulses before drug (squares) and 2 min after 0.5 μM isoprenaline (filled circles). Holding potential −60 mV. *b*, Ratio of peak current after isoprenaline to peak current in control. Cell F05M, total cell capacity 90 pF. Errors caused by voltage drops across the pipette resistance were not responsible for the voltage-dependent enhancement. Series resistance compensation was applied for 3 MΩ out of the total measured resistance of 3.8 MΩ. Thus, the uncompensated ohmic drop across the series resistance was <2 mV at the peak of the current–voltage relationship and much smaller near the reversal potential. Cable artefacts due to the longitudinal resistance of the cells also fail to account for the voltage dependence. Although most of the experiments were done in relaxed cells with cylindrical geometry, we found similar voltage dependence in cells that were deliberately allowed to round up in Ba–TEA solution, even when large, low-resistance pipettes were used and series-resistance voltage drops were <1 mV. *c–e*, Verapamil block of isoprenaline-enhanced currents. Consecutive runs in the absence of drug (trace 1), after exposure to 0.5 μM isoprenaline (trace 2), and after exposure to 50 μM verapamil in the continued presence of isoprenaline (trace 3). Step depolarizations from a holding potential of −60 mV to the test potentials indicated, followed by step repolarization to −40 mV. The capacity transients are blanked for 1.2 ms (*a*), 1.4 ms (*b*) and 2.0 ms (*c*). Noise on records is due to digitization of current traces used for subtraction of linear leak current. Cell F09E. *f*, *g*, Comparison between behaviour of outward currents during depolarization to +120 mV and inward tail currents following repolarization to −40 mV, before (*f*) and after 0.5 μM isoprenaline (*g*). Inward current evoked by depolarization to 0 mV was increased sevenfold (record not shown). Arrow marks time when outward currents in control and isoprenaline runs are approximately equal. Records are blanked for 720 μs following the onset of the repolarizing step to allow for complete settling of capacity transient. Cell F10G.

the outward current remains essentially unchanged. One possibility is that at strongly positive potentials some or all of the channels show a lower conductance after isoprenaline. We cannot rule out an alternative possibility, however, that the amplitude of the tail is severely underestimated in control because it decays within the settling time of the capacity transient.

The present study shows that β-adrenergic stimulation increases the number of functional channels seen with ensemble fluctuation analysis. Isoprenaline slows the settling time constants for activation and inactivation. The enhancement of Ca channel current is largest at weak depolarizations and smallest at strongly positive potentials. These findings with whole-cell recordings may be compared with studies using cell-attached patch recordings.

The large increase in N_F in frog myocytes seems at variance with unitary recordings in mammalian cells, where changes in the apparent number of channels are seen only rarely[24,25] or not at all. It is important to realize, however, that fluctuation

Table 1 Fluctuation analysis of the effect of isoprenaline on the factors that determine Ca channel current

Experimental conditions as in Figs 1, 2. N_F was considered indeterminate if the apparent value of p_{max} fell below 0.20. Average cell capacitance was 57 ± 3.5 pF (mean ± s.e.m.). Con, control; Iso, isoprenaline.

analysis and unitary current analysis can show different biases in the way they assign changes to N and p. This distinction depends on convention and on the time resolution of the measurements[1,7,31]. In our fluctuation analysis, N_F refers to the average number of functional channels readily available to open in response to the test depolarization. Since the analysis is based on differences between adjacent records, a channel is not counted toward N_F during any silent periods much longer than the inter-pulse interval. This definition is consistent with the idea that Ca channels continually undergo transitions between functional (phosphorylated) and nonfunctional (dephosphorylated) states[18], and that the number of channels increases during the β-adrenergic response[2,16,20–22]. N_F is to be distinguished from N_T, the total number of channels in an area of membrane. In a membrane patch, N_T can in principle be determined by counting the maximal number of simultaneous openings during a very long period of recording. We have used N_F to express the idea that channels undergo occasional transitions between functional and nonfunctional conditions, distinct from rapid (millisecond) opening reactions. In single channel recordings, such transitions would presumably give rise to groups of sweeps with no openings.

The slowing of the activation time course was seen in both frog and rat ventricular cells. This might appear surprising, as single-channel analysis in cultured rat ventricular cells has provided convincing evidence that isoprenaline or 8-bromo-cyclic AMP increase the rate constants leading to Ca channel opening[2,23–25]. In fact, the data of Cachelin *et al.*[24] also show a decrease in backward rate constants leading away from the open state. According to our calculations, the net effect predicted from their data is a slowing of activation time course, very much like that seen experimentally (Fig. 3). The agreement leaves open the possibility that after isoprenaline, all channels share the same kinetic properties. This is one of the more critical assumptions of the fluctuation analysis.

The pronounced voltage dependence of the increase in Ca channel current was unexpected because previous studies in multicellular preparations have usually shown equal increases at all potentials (for example, refs 21, 32, 33, but see ref. 8). Differences in the composition of internal or external media are possible factors that cannot be ruled out. The voltage dependence of the β-adrenergic response at relatively weak depolarizations in our experiments seems similar to that seen in single channel recordings (see ref. 2, Fig. 2 and ref. 25, Fig. 5).

The almost complete lack of effect of isoprenaline at strong depolarizations was perhaps our most surprising result. We have considered two alternative explanations. (1) The lack of increase in outward current could be attributed, as already mentioned, to properties of open Ca channels: for example, isoprenaline might recruit channels which show little or no conductance at strongly positive potentials. (2) The large number of channels that are not readily available for activation at +10 mV might become activated at strongly positive potentials even in the absence of β-stimulation. Distinguishing between these hypotheses would be possible if the approach illustrated in Fig. 4*f,g* could be extended to the point of resolving the earliest phase of the tail current.

We thank P. Hess, A. P. Fox and J. B. Lansman for helpful discussion and the USPHS, the American Heart Association and the Miles Institute for support.

Reversible shape change of Triton-treated erythrocyte ghosts induced by Ca^{2+} and Mg-ATP

Yoshinosri Jinbu, Shingo Sato & Makoto Nakao

Department of Biochemistry, Tokyo Medical and Dental University School of Medicine, Yushima, Bunkyo-ku, Tokyo, Japan

The shape of the human erythrocyte depends on intracellular ATP content[1,2] and echinocytic erythrocyte ghosts obtained in the presence of Mg-ATP acquire a diskocytic shape[3–5] after incubation at 37 °C; however, agreement is lacking about the molecular basis of the shape changes. The suggestion that phosphorylation of cytoskeletal structures underlying the membrane is involved[5,6] has been disputed and alternative explanations based on lipid bilayer theory[7,8] and metabolism of phospholipid[9,10] have been proposed. Recently, we re-examined the effect of ATP on the shape of ghosts and found that it consists of two distinct steps[11]. We have, therefore, now examined the effect of physiological concentrations of Ca^{2+} and ATP on the cytoskeleton of the erythrocyte membrane directly using Triton-treated ghosts which had lost this permeability barrier. Our findings suggest that a noncovalent effect of ATP on the cytoskeleton is a prerequisite for shape change.

Untreated ghosts were spherical in 10-mM Tris-Cl buffer. On addition of 10^{-7}–10^{-6} M Ca^{2+} buffer *p*H 7.4, they crenated immediately, but rapidly changed into diskocytes on further addition of 1 mM Mg-ATP (ref. 11). A similar shape change was also observed when Triton-treated ghosts were used. It was clear that these Triton-treated ghosts were not intact for the following reasons: first, the membrane preparation showed decreased amounts of band 3 and 4.2 in SDS-polyacrylamide gel electrophoresis (PAGE) patterns[12] and these bands were recovered in the supernatant instead of the pellet (Fig. 1). Second, Triton-treated ghosts did not shrink in hypertonic sucrose solutions (0.6 M, 0.8 M), demonstrating the absence of an osmotic barrier. Third, in dark-field microscopy, the surface of untreated ghost membranes was smooth, while that of Triton-treated ghosts membranes was rough (Fig. 2); the rough surface seemed to consist of a large number of small particles, as opposed to spicules or small projections. Electron microscopy after negative staining showed a number of small vesicles (diameter 0.08–0.22 μm) and a filamentous network (Tsukita *et al.*, unpublished observation). Fourth, 1% Triton could be used instead of 0.5% Triton, although 1% Triton-treated ghosts were less readily visible.

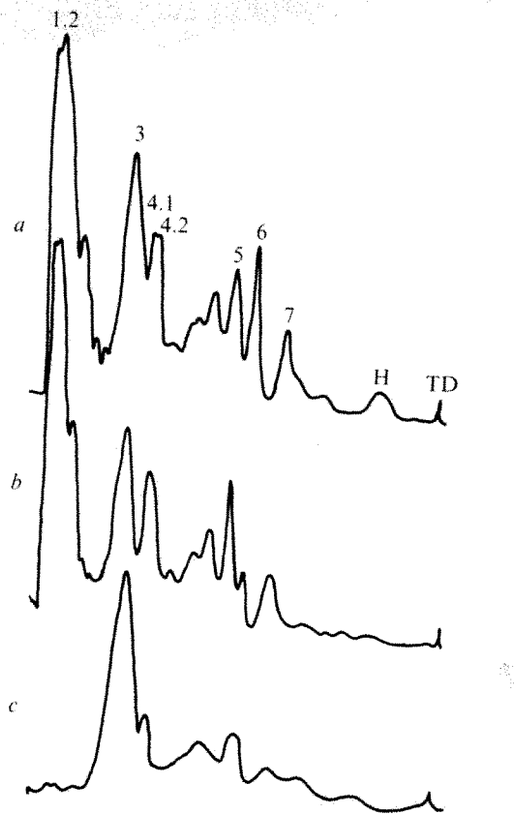

Fig. 1 Densitometric scan of Coomassie blue-stained SDS polyacrylamide gels (5.6%). 10 mM Tris ghosts (*a*), pellet (*b*), supernatant fractions (*c*) derived from 10 mM Tris ghosts after 0.5% Triton treatment. Gels were run and bands numbered accordingly to Fairbanks *et al.*[19]. In each case, 40 μg was applied.
Methods: Human erythrocytes obtained from ACD blood (fresh or preserved for about 4–10 weeks) were washed with physiological saline and haemolysed by 1:50 dilution with 10-mM Tris-HCl buffer, *p*H 7.4, or with 20-mM Tris-maleate buffer containing 1×10^{-3} M $CaCl_2$, and 1×10^{-3} M EGTA, *p*H 7.4 (10^{-6} M Ca^{2+} buffer), at 0 °C, and centrifuged at 18,000 r.p.m. for 20 min at 4 °C. When long-preserved blood was used, the membranes were preincubated for 20 min at 37 °C in 2-mM Mg-ATP solution (*p*H 7.4) (or with 2-mM Mg-ATP in 10^{-6} M Ca^{2+}-buffer). Membranes (converted to diskocytic form by preincubation) were washed with 1 mM $MgCl_2$ at 4 °C (18,000 r.p.m., 20 min). This transformed them to spheres as previously described[11]. Ghosts from fresh cells or pretreated ghosts from preserved blood were mixed with 10 volumes of 1-mM $MgCl_2$ (*p*H 7.4) containing 0.5% Triton X-100. After 5 min at 0 °C, the suspensions were centrifuged at 6,000 r.p.m. for 20 min.

Table 1 Effect of nucleotides and EGTA on the diameters of Triton-treated erythrocyte ghosts shrunk by 10^{-6} M Ca^{2+}

Addition	Diameter μm, $n=30$
None	4.29 ± 0.47
1 mM $MgCl_2$ + 1 mM EGTA	7.53 ± 0.59
1 mM Mg-ATP	6.37 ± 0.63
1 mM Mg-ADP	4.52 ± 0.60
1 mM Mg-GTP	4.51 ± 0.72
1 mM Mg-UTP	4.85 ± 0.55
1 mM Mg-ITP	4.50 ± 0.34

The diameters of Triton-treated ghosts were measured in dark-field light micrographs. Average diameter of ghosts was determined in randomly selected fields and 30 Triton-treated ghosts were measured for each suspension. The preparation of 10^{-6} M Ca^{2+} buffer is described in Fig. 3 legend. Triton-treated ghosts in 10^{-6} M Ca^{2+} buffer were mixed with the indicated solutions at *p*H 7.4, 0 °C and photographs were taken after 10 min at room temperature. When these Triton-treated ghosts were fixed with 1% glutaraldehyde and then 2% osmium tetroxide the results obtained were essentially the same. Both fixatives were dissolved in 10 mM imidazole-HCl and Ca^{2+} EGTA buffer instead of 20 mM Tris-maleate and Ca^{2+} EGTA buffer.

Triton-treated ghosts were larger when prepared with 10-mM Tris-Cl buffer instead of 10^{-6}-M Ca^{2+}-buffer, but shrank for a period of several minutes when suspended in Ca^{2+} buffer (10^{-7}–10^{-6} M) (Figs 2, 3) and became the same size as the Triton-treated ghosts prepared in 10^{-6}-M Ca^{2+} buffer. In fact, shrunken ghosts were spherical and swollen ghosts were diskocytic. These shrunken Triton-treated ghosts swelled on addition of 1 mM Mg-ATP at both 6 °C and room temperature within several minutes (Figs 2, 3) and shrank again after being washed with 1 mM $MgCl_2$ (*p*H 7.4) containing 10^{-6} M Ca^{2+} at both 6 °C and room temperature in the *p*H range, 6.8–7.8. The same shape change was also observed when the incubated Triton-treated ghosts were fixed for 30 min with 1% glutaraldehyde buffered with 10 mM imidazole-HCl (*p*H 7.4) at 0 °C or at room tem-

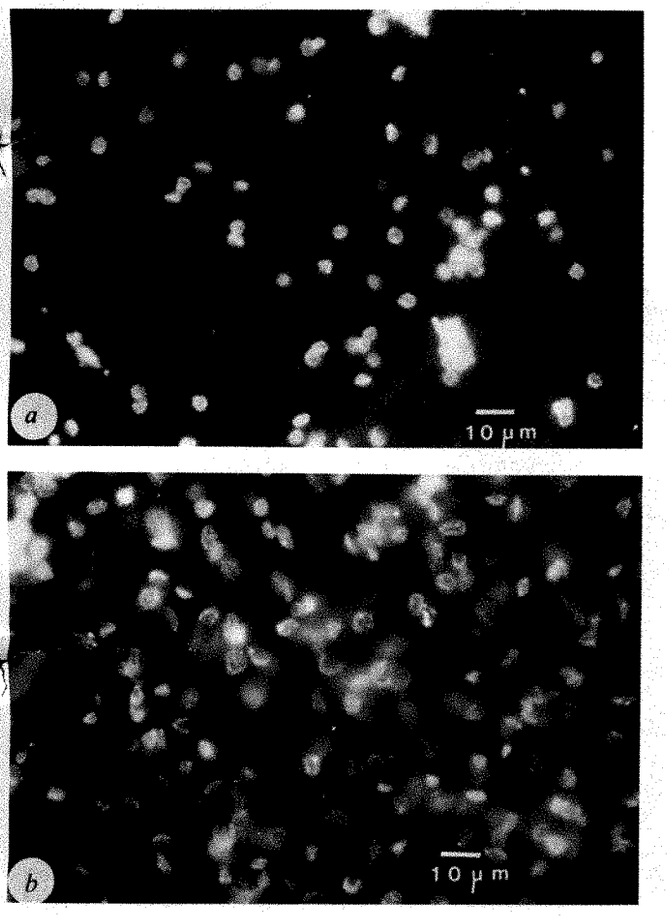

Fig. 2 Dark-field light micrographs of Triton-treated ghosts. The ghosts were prepared with 10 mM Tris-Cl buffer (*p*H 7.4), incubated in 2 mM Mg-ATP (*p*H 7.4) at 37 °C for 30 min, washed with 1 mM $MgCl_2$ (*p*H 7.4) and treated with 0.5% Triton at 0 °C for 5 min. 10 μl of Triton-treated ghosts was dropped into 170 μl of 10^{-6} M Ca^{2+}-buffer at 0 °C (*a*) and 20 μl 10-mM Mg-ATP in 20 mM Tris-maleate buffer (*p*H 7.4) was added at 0 °C (*b*). The shapes of ghosts and Triton-treated ghosts were observed under a dark-field light microscope (Nikon Model S). In 10^{-6} M Ca^{2+}-buffer, Triton-treated ghosts appear to be rough-surfaced small spheres, but on addition of Mg-ATP, they appear to be rough-surfaced disks. These rough-surfaced ghosts seem to be quite different from intact ghosts. The Ca^{2+}-buffer used is described in Fig. 3.

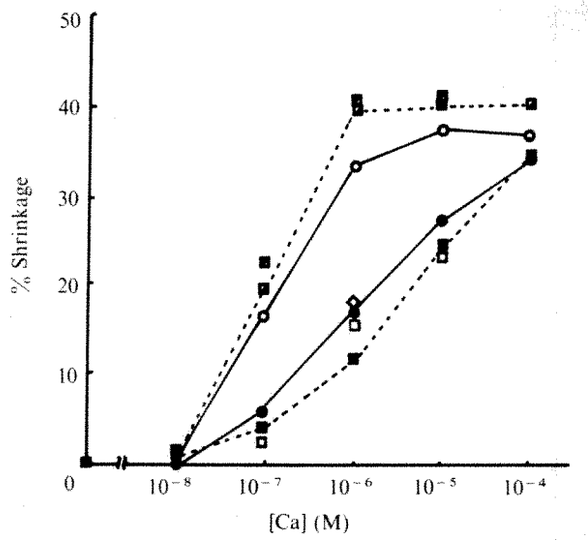

Fig. 3 Effect of Mg-ATP on the shrinkage of Triton-treated erythrocyte ghosts A 10-μl aliquot of Triton-treated ghosts prepared with 10-mM Tris-Cl buffer and 1-mM $MgCl_2$ was mixed with 170-μl Ca^{2+} buffer containing the indicated concentration of Ca^{2+}. ○, Triton-treated ghosts from fresh cells; ●, Triton-treated ghosts from fresh cells on addition of 20 μl 10-mM Mg-ATP; □, Triton-treated ghosts from preserved cells (10 weeks); ◩, Triton-treated ghosts from preserved cells preincubated with adenine and inosine[3]; ◪, Triton-treated ghosts from preserved cells preincubated with 2-mM Mg-ATP after haemolysing and washing, Triton-treated ghosts from preserved cells preincubated with 2 mM Mg-ATP in the presence of 1 mM Mg-ATP; ■, Triton-treated ghosts from preserved cells in the presence of 1 mM Mg-ATP.
Methods: Thirty Triton-treated ghosts were measured as described in Table 1 legend. Shrinkage (%) = $(c-a/c)\times 100$, where c = diameter of Triton-treated ghosts in 1 mM Mg-EGTA solution (*p*H 7.4) a = diameter of Triton-treated ghosts in the indicated Ca^{2+} buffer. Ca^{2+} EGTA buffer was prepared with 20 mM Tris-maleate buffer (*p*H 7.4) containing 0.3 ml 1 mM $CaCl_2$ and various amounts of EGTA as follows in a total volume of 3 ml: Ca^{2+} 1×10^{-8} M, 10 mM EGTA 0.633 ml; Ca^{2+} 1×10^{-7} M, 1 mM EGTA 0.957 ml; Ca^{2+} 1×10^{-6} M, 1 mM EGTA 0.414 ml; Ca^{2+} 1×10^{-5} M, 1 mM EGTA 0.366 ml; Ca^{2+} 1×10^{-4} M, 1 mM EGTA 0.60 ml (ref. 20).

perature and then post-fixed with 2% osmium tetroxide for 30 min at the same temperature. In these experiments, 10 mM imidazole-HCl, Ca^{2+} EGTA buffer was used instead of 20 mM Tris-maleate buffer[13]. Since fixation by 0.5–2% glutaradehyde was not completed in 30 min at 0 °C, we could not determine the exact time required for the shape change. Mg-pyrophosphate, Mg-UTP, Mg-GTP, Mg-ITP, Mg-adenylyl-imidodiphosphate(AMPPMP) and Mg-adenylyl-(β-γ)methylene diphosphate(AMPPCP) were not effective (Table 1) in reversing Ca^{2+}-mediated shrinkage. In the absence of ATP, low concentrations of Ca^{2+} induced shrinkage of the Triton-treated ghosts: the $K_{0.5}$ for Ca^{2+} was about 10^{-7} M, in contrast with the relatively high value of 3×10^{-6} M in the presence of ATP (Fig. 3). Triton-treated ghosts, like untreated ghosts, could change shape reversibly depending on Mg-ATP in the presence of 10^{-6} M Ca^{2+}.

The results described above showed that crenation or disk formation of ghosts occurred in hypotonic solutions with low concentrations of Ca^{2+} or Mg-ATP, respectively, and the shrinking or swelling, respectively, of Triton-treated ghosts occurred in the same conditions. Therefore, crenation of ghosts corresponds to the shrinkage of Triton-treated ghosts, and disk formation of ghosts, to the swelling of Triton-treated ghosts. When isotonicity was restored by adding KCl or NaCl, Triton-treated ghosts shrank immediately and did not respond to either Ca^{2+} or Mg-ATP, agreeing with results reported by Johnson *et al.*[14]. Since shrinking and swelling of Triton-treated ghosts were fast, even at 6 °C, and Triton-treated ghosts lost the permeability barrier, Mg-ATP must act on the cytoskeleton directly and the effect is essentially different from phosphorylation of lipid and protein. The effect of Mg-ATP might not be due to removal of Ca^{2+}, because the shape change occurred even in the presence of 3×10^{-3} M EGTA + 3×10^{-3} M Ca^{2+}, although a nominally equimolar mixture of Ca^{2+} and EGTA will have an indeterminate Ca^{2+} concentration. The sensitivity to Ca^{2+} presumably does not depend on calmodulin because most of calmodulin is lost in the membranes during preparation of ghosts[15] and calmodulin inhibitors[16] (chlorpromazine, trifluoperazine and W-7) did not inhibit this Ca^{2+}-induced shrinking (not shown).

Figure 3 shows that phosphorylation of the Triton-treated ghosts seems to be correlated with the Ca^{2+}-induced shrinking and ATP-induced fast swelling. Both Triton-treated ghosts from fresh cell ghosts without preincubation and from preserved cell ghosts preincubated with Mg-ATP (Fig. 3) were highly sensitive to Ca^{2+} in the absence of Mg-ATP. On addition of Mg-ATP, both of them became relatively insensitive to Ca^{2+} (Fig. 3). However, Triton-treated ghosts from preserved cells without preincubation were not highly sensitive to Ca^{2+} with or without the addition of Mg-ATP (Fig. 3). After alkaline phosphatase treatment of fresh cell ghosts[6], their Triton-treated ghosts became less sensitive to Ca^{2+} ions, and then they recovered Ca^{2+} sensitivity by re-incubation with 2-mM Mg-ATP for 20 min at 37 °C (Table 2).

Table 2 Ca^{2+} sensitivity of Triton-treated erythrocyte ghosts

Source	Pretreatment of intact ghosts	Addition of Mg-ATP	Shape	Ca^{2+} sensitivity
Fresh	None	+	Swell	Low
		−	Shrink	High
	Phosphatase*, wash	+	Swell	Low
		−	Swell	Low
	Phosphatase + P_i*, wash	+	Swell	Low
		−	Shrink	High
	Phosphatase, wash then reincubated with Mg-ATP	+	Swell	Low
		−	Shrink	High
	Heat-denatured phosphatase	+	Swell	Low
		−	Shrink	High
Preserved	None	+	Swell	Low
		−	Swell	Low
	Preincubation† with Mg-ATP	+	Swell	Low
		−	Shrink	High

* Ghosts in a haematocrit of 50% in 10-mM Tris-Cl buffer (*p*H 7.4) incubated with 0.2 mg per ml alkaline phosphatase (*Escherichia coli*, Sigma III R) with and without 10-mM P_i at 4 °C for 20 min as described Birchmeier and Singer[6].

† Preincubation was carried out with 2 mM Mg-ATP at 37 °C for 20 min.

‡ K_m values for Ca^{2+} were roughly 10^{-7} M (High) and 10^{-6} M (Low).

We expected that preserved cell ghosts were dephosphorylated, but that fresh cell ghosts, as well as old cell ghosts treated with Mg-ATP, could be phosphorylated. Direct measurement supported this. The amounts of phsophate in lipid and protein of Triton-treated ghosts were determined after extracting extensively with chloroform, methanol and 1.2 M HCl (10:10:1). Although the phosphate content of lipid was almost constant (about 17 μg per mg protein), the phosphate content of protein was gradually decreased from 0.63 μg per mg protein to 0.25 μg per mg protein during preservation (1–13 weeks). Dephosphorylation of membrane protein seemed to occur during storage. Phosphorylation of membrane protein with 1 mM Mg-ATP^{32} was reported by various investigators[17,18]. In this experiment, preincubation with 1-mM Mg-[γ-^{32}P]ATP (specific radioactivity 1.3×10^7 c.p.m. per μmol of ATP) at 37 °C for 30 min resulted in labelling of the ghosts with ^{32}P ($\sim2.6\times10^4$ c.p.m.), and about 85% of this ^{32}P (about 2.3×10^4 c.p.m.) was removed by Triton treatment. The remaining 15% of the label was present in the Triton-treated ghosts (122 pmol per mg protein), although 50% of phospholipids was removed after Triton treatment. After extensive extraction with acid/chloroform/methanol the ^{32}P content of the membrane was 36 pmol per mg protein. Since the value, 122 pmol per mg, is so small compared with the total ghost phospholipid, 1×10^6 pmol per mg protein, it is not likely that the phosphorylation of lipid is more important than phosphorylation of protein.

We consider that this shrinking and swelling of Triton-treated ghosts involve effects produced on the cytoskeleton at physiological concentrations of Ca^{2+} and ATP and that phosphorylation of cytoskeleton and a noncovalent effect of ATP on cytoskeleton are the basis of this phenomenon.

Viscoelastic properties of erythrocyte membranes in high-frequency electric fields

H. Engelhardt, H. Gaub & E. Sackmann

Physik Department, E22, Technische Universität München, D-8046 Garching/München, FRG

The high deformability of erythrocytes which is essential for their transport through the capillaries depends critically on their discoid shape and on the elasticity of the plasma membrane, which may be determined by interactions of the cytoskeleton, the lipid/protein leaflet and the glycocalyx. Although techniques exist for measurement of the static elastic properties of erythrocytes, the cells are continuously deformed *in vivo*, the stress varying within periods of a few seconds. Thus dynamic elastic behaviour is essential for their physiological function. We present here a novel means of measuring the dynamic elastic constants of the red cell based on the transient deformation of individual cells in an inhomogeneous high-frequency (HF) electric field. By microscopy it is possible to record cellular elongations as small as 200 nm occurring within time scales of 1 ms. A main advantage is that the cellular response is linear and thus can be more readily interpreted theoretically. We have observed a creep function consisting of two exponentials with response times of 0.1 s and 1 s, which can be described in terms of a simple viscoelastic model. A remarkable temperature dependence of the membrane elasticity between 25 °C and 15 °C is observed for freshly drawn cells but not for trypsinized ones.

Blood was freshly drawn from the fingertip and diluted in 1 mM phosphate buffer (*p*H 7.5), containing 300 mM D-mannitol and 5 mM glucose. For the trypsin treatment the cells were incubated at 37 °C for 30 min after addition of 10 p.p.m. trypsin and 4 p.p.m. EDTA to the solution. The cell suspension was placed between two electrodes with sharp edges (Fig. 1*a*). Due to the different conductivities of the cytoplasm ($\sigma_i = 1\Omega^{-1}\,m^{-1}$) and the external medium ($\sigma_a = 10^{-2}\,\Omega^{-1}\,m^{-1}$) the behaviour of the cells in the inhomogeneous field depends on the frequency, *f*, in the following way[1]. At $f > f_2(\sim10^7\,Hz)$ both media behave like insulators and the cells swim freely. At $f_1(\sim10^5\,Hz) < f < f_2(\sim10^7\,Hz)$ the conductivity of the cytoplasm can no longer be neglected. This leads to the accumulation of opposite charges at the two ends of the cell opposing the electrodes as indicated in Fig. 1*b*. Due to this so-called Maxwell–Wagner polarization[1] the cell behaves as an electric dipole and couples to the electric field. At $f < f_1$ the cells start to rotate about an axis parallel to the edges of the electrodes. In contrast to Holzapfel *et al.*[2] we observe the rotation of individual cells[3].

For the experiments the frequency is adjusted to a certain value within the second frequency regime. The cells are attracted to one of the electrodes by a bias field of $10^4\,V\,m^{-1}$. For the deformation the amplitude is suddenly increased to 2×10^4–$10^5\,V\,m^{-1}$ for 2.5 s and is then reset to the original value. The time-dependent elongation of the cell—the so-called creep function, $C(t)$—as well as the decay in the original shape, are measured microscopically as shown in Fig. 1.

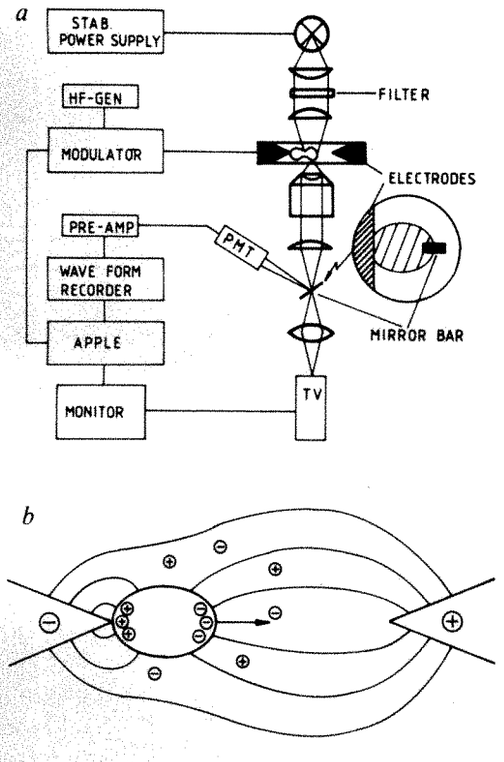

Fig. 1 *a*, Schematic view of an experimental device used to measure the creep ($C(t)$) and decay ($R(t)$) functions after application of a high-frequency field jump. The electrodes are made of commercial razor blades. The curvature of their edges is about 0.5 μm and the electrode distance is 50 μm. *b*, Schematic view of electric field lines and charge accumulation within the cell. This is due to the Maxwell–Wagner polarization which arises as a consequence of the different conductivities of the cytoplasm ($\sigma_i = 1\Omega^{-1}\,m^{-1}$) and that of the outside medium ($\sigma_0 = 10^{-3}\Omega^{-1}\,m^{-1}$). **Methods:** Deformation was achieved in the frequency range 5×10^5–2×10^6 Hz if the conductivity of the outside medium was adjusted to $\sigma_0 = 10^{-2}\Omega^{-1}\,m^{-1}$. The cells were fixed to one of the electrodes by a bias voltage of 1 V. For the transient deformation, field jumps of 2–5 V amplitude and ~2.5 s duration were applied. The HF field was generated by a sine generator equipped with a computer-controlled amplitude modulation. A modified Zeiss Axiomat microscope and a Zeiss oil immersion objective (type Planapo 1.3; oil Pol∞/017) (×100) were used. Bright-field illumination at 410 nm was supplied by a halogen lamp driven by a stabilized power supply. An image of the object was projected onto a TV camera, which allowed certain cells to be selected and observed during measurement. The deformation was measured with a bar-like mirror, deposited on a glass plate, positioned in the focal plane of the objective. The light reflected by this mirror was focused on a photomultiplier (RCA 931 b). If the cell is elongated, the light intensity at the photomultiplier is decreased, the decrease in intensity being proportional to the elongation of the cell. The photomultiplier output is first amplified and then fed into a waveform recorder (Biomation model 1015). From there, the signal is transferred to an Apple microcomputer for signal averaging up to 256 events.

Figure 2 shows typical response curves for a freshly drawn cell (Fig. 2*a*) and for a cell treated with trypsin. Both the creep ($C(t)$) and the decay ($R(t)$) functions exhibit a fast and a slow component. $C(t)$ can be well represented by

$$C(t) = A_0 - A_1 e^{-t/\tau_1} - (A_0 - A_1) e^{-t/\tau_2} \qquad (1)$$

A similar equation holds for $R(t)$. A quantitative evaluation of the experimental curves shows that the time dependencies of $C(t)$ and $R(t)$ are slightly different. This is due to the electric field inhomogeneity through which the force decreases with the degree of elongation (Fig. 3).

As shown in Fig. 2*a*, the maximum amplitude A_0 at 13 °C is smaller by a factor of 5 than at 30 °C. This effect has been observed for 9 out of 10 cells. It is reversible if the temperature is increased and decreased several times. Obviously, this remarkable temperature dependence is not observed for trypsinized cells (Fig. 2*b*). For a first quantitative evaluation of the viscoelastic response curves, it is helpful to introduce a viscoelastic model. As $C(t)$ and $R(t)$ consist of a fast and a slow process, the model of Fig. 3*b* is used[4]. A different model proposed by Rand[5] is adapted to the behaviour of cells at large deformations and long time scales. Our model is characterized by four parameters: two spring constants (μ_1, μ_2) and two viscosities (γ_1, γ_2) which can be determined as follows.

The amplitudes and relaxation times of equation (1) are expressed in terms of the four parameters of the model and the force F_0 by solving the differential equations of the model (Fig. 3) using standard procedures. The parameters are then determined by fitting the theoretical functions $C(t)$ (and $R(t)$) to the experimental response curves. This was done using an Apple computer by the Newton procedure. Finally, μ_1, μ_2, γ_1 and γ_2 are determined in units of the force F_0. Since F_0 cannot be measured yet, it has been estimated in the following way. For $f_1 < f < f_2$ the electric field, E_i, inside the cell is small compared with that at the outside, E_0, since $\sigma_i \gg \sigma_0$. F_0 is obtained by integrating the Maxwell tension over the surface area A of the cell and by time averaging. It is given approximately by: $F_0 \sim 1/4\,\varepsilon_0\varepsilon \times E^2 A$. For $\varepsilon = 80$, $A = 10\,\mu m^2$ and $E_a \sim E_0 = 10^5\,V m^{-1}$ one obtains $F_0 \sim 2\times10^{-11}$ N. The absolute values of the parameters in Table 1 hold for this value of F_0. The spring constant μ_1 is directly given by the maximum amplitude (which was adjusted to ~1 μm) according to

$$\mu_1 = A_0 F_0 = 2\times10^{-5}\,N\,m^{-1} \qquad (2)$$

μ_1. A measure of the elastic modulus of the cell, is of the same order of magnitude as the elastic shear modulus ($7\times10^{-6}\,N\,m^{-1}$ at 25 °C) obtained with the micropipette method[6–8].

To account for the two exponentials of $C(t)$, the model must contain two dash pots and two springs. A manifold of other arrangements would account for the response function. The model was chosen for its simplicity. To describe the membrane viscoelasticity in terms of extensive elastic constants it is necessary to determine the change of the cellular shape quantitatively. Following Hochmuth *et al.*[7] and Waugh[9], an upper limit on the surface viscosity of the plasma membrane may be estimated according to $\eta = \mu \times \tau$. The value of $\gamma = 3\times10^{-6}\,N\,s\,m^{-1}$ is again of the same order of magnitude as that obtained with the micropipette technique: $7\times10^{-7}\,N\,s\,m^{-1}$ (refs 7, 8). It is, however, two orders of magnitude higher than the surface viscosity of the lipid protein bilayer of the red cell as obtained from lateral diffusion studies[9,10]. This shows that the membrane

Table 1 Amplitudes (A_0, A_1), relaxation times (τ_1, τ_2), spring constants (μ_1, μ_2) and viscosities (γ_1, γ_2) for normal and trypsinized cells.

Type of cell	Temperature (°C)	A_0 (μm)	A_1 (μm)	τ_1 (s)	τ_2 (s)	μ_1 (10^{-5} N m^{-1})	μ_2 (10^{-5} N m^{-1})	γ_1 (10^{-6} N m^{-1})	γ_2 (10^{-6} N m^{-1})
Normal	30	1	0.3	0.16	0.9	1.0	0.74	3.7	2.9
	16	0.2	—	—	—	—	—	—	—
Trypsinized	30	1	0.64	0.1	0.9	1.0	0.48	1.7	2.4
	14	1.1	0.45	0.1	0.9	1.1	1.25	2.6	3.8

The absolute values hold for an external force of $F_0 = 2\times10^{-11}$ N.

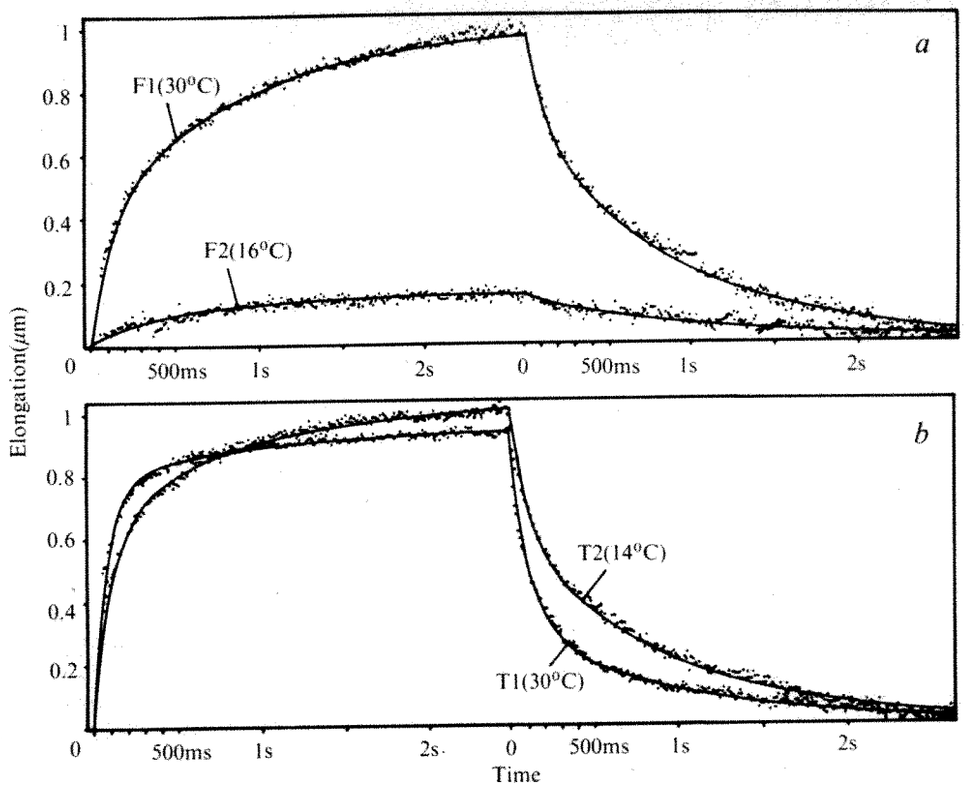

Fig. 2 *a*, Response curves of freshly drawn erythrocytes obtained after application of field jumps of 5 V, $f = 6 \times 10^5$ Hz. The maximum elongation is $A_0 = 1$ μm at 30 °C and $A_0 = 0.21$ μm at 16 °C. The number of repetitions $n = 10$. *b*, Comparison of response curves of trypsinized cells obtained at 30 °C and 14 °C. The frequency is the same as in *a*, voltage 6 V, repetition number $n = 10$, maximum amplitude $A_0 = 1$ μm at both temperatures.

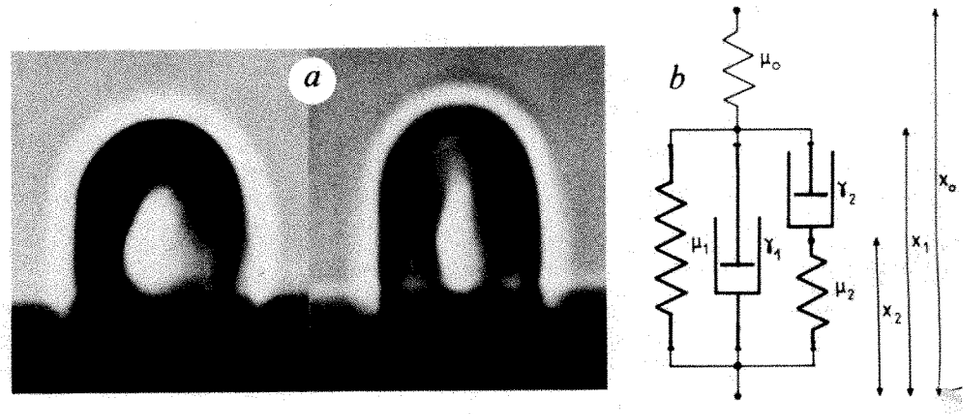

Fig. 3 *a*, Photomicrograph of a cell in the presence of a small bias high-frequency field (left) and after increasing the field strength to 10^5 V m^{-1} which leads to a reversible deformation of the cell (right). Note that the cells have a discoid shape in both cases. *b*, Viscoelastic model of a red blood cell membrane consisting of a parallel arrangement of a Maxwell body (right) and a Voigt body (left). The following notations are used: μ_1, μ_2, stiffness constants of springs; γ_1, γ_2, viscosities of the dash pots; x_1, x_2, elongations of springs of Voigt body and Maxwell body, respectively. The spring having the stiffness constant μ_0 has been introduced to account for the fact that the force F_0 is proportional to the elongation x_1 of the blood cell due to the inhomogeneity of the electric field. The model obeys the following differential equations: $\gamma_1 \dot{x}_1 = F_0 - \mu_1 x_1 - \mu_2 x_2$ and $\gamma_2 \dot{x}_2 = \gamma_2 \dot{x}_1 - \mu_2 x_2$.

viscoelasticity is largely determined by the glycocalyx and the spectrin–actin cytoskeleton which are both coupled to the bilayer[11,12].

The technique described here enables time-resolved measurements in the linear range of deformation and the application of simple equations of viscoelasticity[4]. This is a major advantage compared with the micropipette method[5,6,7] and tether formation[9] or the techniques based on the cellular deformation in viscometric flows[12,13], where non-linear effects have a dominant role. The electric fields are well below the limit of dielectric breakthrough[15,16] and the forces involved ($F_0 \sim 2 \times 10^{-11}$ N) are very weak. The field jump technique thus bridges the gap between the non-disturbing methods, based on the frequency analysis of thermally excited membrane undulations[17–19], and the strongly disturbing techniques mentioned above.

Effect of IFN-γ on the immune response *in vivo* and on gene expression *in vitro*

Masataka Nakamura, Tim Manser, Gregory D. N. Pearson, Michael J. Daley & Malcolm L. Gefter

Department of Biology, Building 56–701, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

T lymphocytes produce a variety of immunoregulatory molecules including gamma interferon (IFN-γ)[1–3] and antigen-specific suppressor and enhancer factors[4–7]. During our studies of active substances obtained from cloned T-cell lines, we observed that certain fractions administered to mice resulted in enhancement of immune responses. Preliminary characterization of the substance suggested that it could be IFN-γ and we therefore undertook a study of the action of IFN-γ produced by recombinant DNA methodology on immune responses. We found that for several antigens, administration of IFN-γ to mice leads to two- to five-fold enhancement of antibody formation provided that the IFN-γ and antigen are administered together. The effect was dose dependent, giving a maximal response at 500–600 anti-viral units per mouse. Preliminary studies suggest that the macrophage may be the target of IFN-γ action. Addition of IFN-γ to cultures of a macrophage cell line leads to a greater than 10-fold increase in the level of RNA coding for *I*-region-encoded cell surface molecules.

Various doses of murine IFN-γ, produced by monkey cells transfected with a simian virus 40 (SV40)-based expression vector containing the murine IFN-γ gene, were injected into BDF_1(B6XDBA/2) mice along with the antigen hen egg lysozyme (HEL) or the antigen dinitrophenol-conjugated bovine γ-globulin (DNP-BGG). Administration of IFN-γ affected indirect plaque-forming cell (PFC) responses to both HEL and DNP in a similar dose-dependent manner. A two- to five-fold enhancement of PFC was observed when 500–2,000 units of IFN-γ were administered (Fig. 1*a* and *b*). Administration of doses as high as 6,700 or as low as 100 anti-viral units per mouse did not significantly alter the PFC response. Stimulation of the PFC response (direct plaques) using 1,000 units per mouse was also observed with the antigen sheep red blood cells (data not shown). Preparations of IFN-γ derived from independently transfected monkey cells were equally active and showed the same dose–response curve.

The enhancement of the PFC response observed might have been due to recruitment of responding cells to draining lymph nodes, rather than to an actual increase in the number of reactive cells[8]. If the total number of PFC per animal remained unchanged then one would expect that the total antibody secreted per animal would remain constant. Accordingly, serum titres of treated mice were examined. Five mice were injected with 250 units of IFN-γ or phosphate-buffered saline (PBS) on both the day of immunization with the antigen HEL and again on the following day. Individual mice were bled 12 days after immunization and the amount of antibody specific for HEL was determined by radioimmunoassay (monoclonal antibody to HEL was used as a standard). The control group had an average of 1.0 mg ml^{-1} of anti-HEL antibody whereas the IFN-γ-treated group had an average of 3.4 mg ml^{-1}. The stimulation index of 3.4 agrees with that observed in PFC responses. The range of stimulation indices for individual mice was 1.5–9.2.

The IFN-γ preparations used above contained components of fetal calf serum as well as cellular components secreted by monkey cells. To examine whether the enhancement of the PFC response by IFN-γ preparations was mediated by IFN-γ itself, the preparations were passed over a column containing anti-IFN-γ immunoglobulin. As seen in Table 1, the stimulating activity was removed by such a treatment but could be subsequently recovered from the column. Similarly, the stimulating activity was sensitive to *p*H 2.0, a property of IFN-γ (see Table 1). Direct evidence that the enhancement activity was exclusively due to INF-γ was obtained by using murine IFN-γ isolated from *Escherichia coli* cells expressing a mouse IFN-γ gene. These data are shown in Fig. 1*c* and *d*. Two- to four-fold enhancement of PFC responses to HEL and DNP was observed upon administration of IFN-γ at the same doses used earlier. These results strongly indicated that the increase in the PFC response was due to the IFN-γ molecule itself.

To gain some insight into the mechanism of enhancement of antibody formation, we studied the effect of altering the time of administration of IFN-γ relative to antigen challenge. Administration of IFN-γ at the same time as immunization was the most effective (Table 2). Administration of IFN-γ 1 and 2 days before immunization resulted in some stimulation of the anti-HEL response whereas no enhancement was observed if IFN-γ was given on both day 3 and 4 after immunization. This result suggests that perhaps some early step of the immune response such as antigen processing by macrophages could be affected by IFN-γ. IFN-γ, produced by recombinant DNA technology as well as T cells stimulated with mitogens, has been shown to have profound effects on macrophage-dependent cell killing[9–11] and on expression of cell surface molecules associated

The monkey cell-derived IFN-γ was passed through a column of Sepharose-4B (Pharmacia) conjugated with anti-IFN-γ globulin (Enzo Biochemical, New York). The material absorbed to the column was eluted with 4 M NaCl. Effluent and eluate were dialysed against 100 volumes of PBS for 24 h. For acid treatment of IFN-γ, the samples were dialysed against either sodium acetate buffer (*p*H 2.0) or PBS (*p*H 7.3) for 16 h and were then dialysed against PBS for 24 h. Procedures for immunization, IFN-γ injection and PFC assay were as described in the legend to Fig. 1. HEL was used as an antigen. Units in parentheses indicate the amount of IFN-γ equivalent to those contained in a given volume before treatment. SI, stimulation index; *P*, probability; NS, not significant.

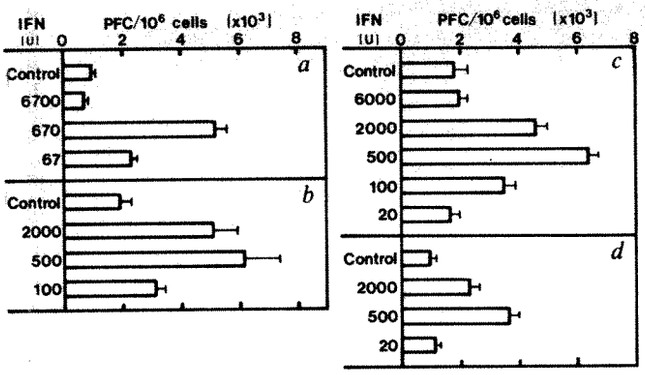

Fig. 1 Effect of IFN-γ on the plaque-forming cell response of mice. Eight- to 12-week-old BDF_1 mice (Jackson Laboratories, Bar Harbor) were immunized with either 100 μg of HEL (graphs *a* and *c*) or DNP-BGG (graphs *b* and *d*) in complete Freund's adjuvant intraperitoneally. The INF-γ preparations, which were supplied by Genentech Inc. (South San Francisco), were culture supernatants (20,000 U ml^{-1}) of the monkey cells transfected with an SV40-based expression vector containing a mouse IFN-γ gene (the approach to its production was basically that which has been reported for the production of cloned human IFN-γ)[16] and a product purified from *E. coli* harboring an expression vector that contained murine IFN-γ cDNA (specific anti-viral activity of 8×10^6 U per mg protein)[17]. Left (*a* and *b*) and right (*c* and *d*) graphs show the results obtained by using the monkey cell-derived and the *E. coli*-derived IFN-γ, respectively. The mice were injected intravenously with various doses of IFN-γ diluted in 0.5 ml of PBS. Injections were on both the day of immunization and the following day. Doses reported are the total amount administered. The control group received 0.5 ml of PBS intravenously. Eight days after immunization a PFC assay was carried out using cells of parathymic lymph nodes for the HEL response or spleen for the DNP response according to a modified method of Jerne[18]. HEL- or trinitrophenol-conjugated sheep red blood cells (SRBC) (Scott Laboratories, Fiskeville, Rhode Island) were used as indicator cells. Lyophilized guinea pig serum (Colorado Serum Co.), absorbed on SRBC, was used as a source of complement at a final dilution of 1:40. Rabbit anti-mouse immunoglobulin serum was used at a final dilution of 1:400 to detect IgG PFC. Each bar represents the average PFC response of five mice plus the standard error (s.e.).

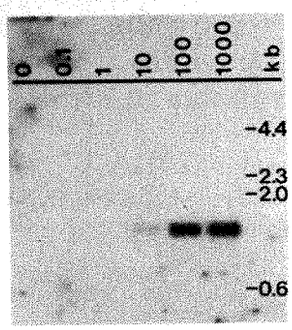

Fig. 2 Increase in the level of *I*-region-encoded RNA due to the addition of IFN-γ to the culture medium of the mouse macrophage cell line P388D1. The DBA/2-derived macrophage cell line P388D1 (ref. 19) was grown in monolayer culture to approximately 30% confluence, whereupon various amounts of *E. coli*-derived murine IFN-γ were added directly to the medium. The cells were then incubated at 37 °C for 48 h and collected. Total cellular RNA was prepared from each cell sample as previously described[20,21]. 15 μg of each RNA sample were glyoxalated, electrophoresed in a 1.2% agarose gel and transferred to nitrocellulose as described[22]. The nitrocellulose filter was then baked for 2 h at 80 °C under vacuum and hybridized (in a buffer containing 50% formamide, 5×SSC and 10% dextran sulphate) at 42 °C for 20 h with an *I*-region (A^d_α) cDNA clone probe (labelled with ^{32}P via nick-translation) which was kindly provided by Dr Mark Davis, NIH. After multiple washings in 2×SSC at 65 °C the filter was exposed to X-ray film for 48 h using intensifier screens. The resulting autoradiogram is shown. The positions of molecular weight standards run in an adjacent lane (not shown) are indicated. Lane 1, no IFN-γ added; lane 2, IFN-γ added to a final concentration of 0.1 anti-viral units per ml culture medium; lane 3, 1 unit per ml; lane 4, 10 units per ml; lane 5, 100 units per ml; lane 6, 1,000 units per ml. The size of the hybridizing band (1.2 kb) is that expected for $I\text{-}A_\alpha$ mRNA.

with antigen presentation[12–14]. Also it has been reported that recombinant human IFN-γ increases synthesis of HLA-DR molecules on human melanoma cell lines[15]. It may be that one of the biological functions of IFN-γ is to convert macrophages from an inactive to an active state, thereby promoting antigen presentation and hence immune responses.

We tested the effect of the bacteria-derived IFN-γ on the expression of *I*-region-encoded antigens in a macrophage cell line, P388D1. As seen in Fig. 2, treatment of cultured cells with doses of IFN-γ of 10–1,000 units ml^{-1} leads to a profound increase in the level of expression of RNA derived from the I-region. The effect was dose dependent and suggests that IFN-γ may act by inducing synthesis of mRNAs that encode proteins involved in antigen processing and presentation.

We have shown that IFN-γ is an immunoregulatory agent as assayed *in vivo* using recombinant DNA-generated preparations. The ability of IFN-γ to enhance the level of induced antibodies was seen with several antigens. The time-dependent nature of the phenomenon suggests that an early step in the immune response is affected. The induction of *I*-region-specific RNA seen in a macrophage cell line suggests that this early step may be antigen processing and/or presentation. Interferon may be a general enhancer of other differentiated functions within the immune system. We are currently investigating whether IFN-γ has demonstrable physiological effects on T and B cells. The basis of stimulation of *I*-region-derived mRNA is also being studied.

We acknowledge Genentech Inc. for providing the recombinant IFN-γ. We also thank Dr Daniel Capon of Genentech for his help and Audrey Childs for the preparation of this manuscript. Surface dynamics of the integral membrane protein bacteriorhodopsin

Max A. Keniry, H. S. Gutowsky & Eric Oldfield

School of Chemical Sciences, University of Illinios at Urbana-Champaign, 505 South Mathews Avenue, Urbana, Illinois 61801, USA

Recently, there has been great interest in determining the three-dimensional structures of membrane proteins, particularly bacteriorhodopsin, for which a variety of possible folding arrangements have been suggested[1–4]. In this paper we present nuclear magnetic resonance (NMR) spectra[5–8] of deuterated bacteriorhodopsin, and use the data to help interpret the various suggested bacteriorhodopsin folding patterns. The results strongly indicate that (1) a membrane surface (±1 residue) may be defined by NMR in bacteriorhodopsin; (2) all amino acids inside the surface are essentially crystalline; (3) all amino acids outside the surface (surface residues) in bacteriorhodopsin are highly mobile on the time scale of the ^{2}H NMR experiments; (4) NMR data may be used to help evaluate the various structural models that have been proposed; (5) aggregation of purple membrane sheets may lead to an immobilization of the surface residues.

In Fig. 1 *A–I*, we show ^{2}H NMR spectra of a variety of ^{2}H-labelled bacteriorhodopsin samples. In all cases, the spectrum observed consists of a sharp central component and a broad powder pattern. The central component arises, we believe, from surface residues in bacteriorhodopsin. Observation of this component requires acquisition of at least 2,000–4,000 data points, Fig. 1, *J–M*, to avoid truncation effects and its 'disappearance'. The component can then be quantified by means of computer simulation.

The central components arise from deuterons that reorient over a wide angular range in a time several-fold less than the inverse of the frequency of the rigid lattice quadrupolar splitting, that is, $\tau_c \ll 10^{-5}$ s. In principle, the deuterium could be in very mobile surface residues, in isotropically tumbling membrane fragments, or perhaps in residual HO^{2}H in our sample. We rule out the possibility that residual HO^{2}H is a significant contributor to the central component because additional exchanges of the samples with ^{2}H-depleted water do not reduce the intensity of the central component, and the absolute intensity of a corresponding unlabelled membrane sample, exchanged with ^{2}H-depleted water, is negligible. All samples (with different labelling of the amino acids by ^{2}H) contain essentially the same protein/water ratios, having been exchanged three times with deuterium-depleted water by centrifugation (for 14 h at 130,000*g*) followed by resuspension in deuterium-depleted water (200 mg membrane per 5 ml water), but the intensity of the central component varied widely. Even lyophilization and resuspension in ^{2}H-depleted water does not change the intensity of the isotropic components (data not shown).

We rule out the possibility that the central components arise from isotropically tumbling membrane fragments since then the isotropic/rigid ratios should be the same for each labelled amino acid, which is not the case. Instead, there is a strong correlation between the position of the residue within the purple membrane postulated by the various experimental and theoretical models[1–4], and the intensity of the central component resonances of Fig. 1 *A–I*. We thus ascribe at least 90–95% of the intensity of the central component to surface residues undergoing fast isotropic motion.

In Fig. 2 we show the folding pattern of bacteriorhodopsin in the purple membrane of *Halobacterium halobium* postulated recently be Engelman *et al.*[4]. To interpret our ^{2}H NMR results, we define a membrane surface, designated B in Fig. 2. Residues to the outside of line B are surface residues, which we assert will be mobile on the ^{2}H NMR timescale (giving the central 'isotropic' components, Fig. 1, *A–I*), while residues inside of line B will be rigid, or crystalline, and lead to the broad powder-pattern line shapes of Fig. 1. Similarly, we define two alternative membrane surfaces, A and C, which are two residues outside or inside of line B respectively. The earlier models of Engelman *et al.*[1], Ovchinnikov[2] and Khorana[3] may be treated similarly, to define various possible membrane surface planes.

We show in Fig. 3 *A–D*, the correlations we have obtained, for a selection of deuterium-labelled amino-acids, between the percentage of the residues located on the surface of bacteriorhodopsin (for a particular model, refs 1–4), and the percentage of the total ^{2}H signal intensity of the isotropic component (mobile, surface residues) obtained from simulations of the spectra of Fig. 1 (and data at 37 °C for Phe, Tyr and Arg, not shown). There is a significant correlation for all models, Fig. 3 and Table 1. The earliest model of Engelman *et al.* (ref. 1, Fig. 3*A*) has the poorest agreement with the ^{2}H NMR results. We predict a theoretical slope (m) of 1.0, for a 1:1 correspondence between percent surface residues and percent isotropic component, while the model gives $m = 1.12$ with a correlation coefficient $\rho = 0.80$. The later models of Ovchinnikov (Fig. 3*B*), Khorana (Fig. 3*C*) and Engelman (Fig. 3*D*) all give considerably better agreement (Table 1). Each part of Fig. 3 includes the perfect agreement, theoretical line ($m = 1$, $c = 0$).

We have also examined each of the published bacteriorhodopsin models using changes in surface definition of ±1, and ±2 residues. The results indicate that the originally proposed surfaces gave the best fit (Table 1). As an example, we show in Fig. 3*E* typical results for the Engelman/82 model[4]. For a +2 and a −2 residue change in surface definition the correlation with the NMR results is much poorer (+2, $m = 0.69$, $c = -2.1$, $\rho = 0.69$; −2, $m = 1.25$, $c = 10.8$, $\rho = 0.68$).

Table 1 Correlation between the number of surface residues predicted for various theoretical models of bacteriorhodopsin structure and the experimental ^{2}H NMR results

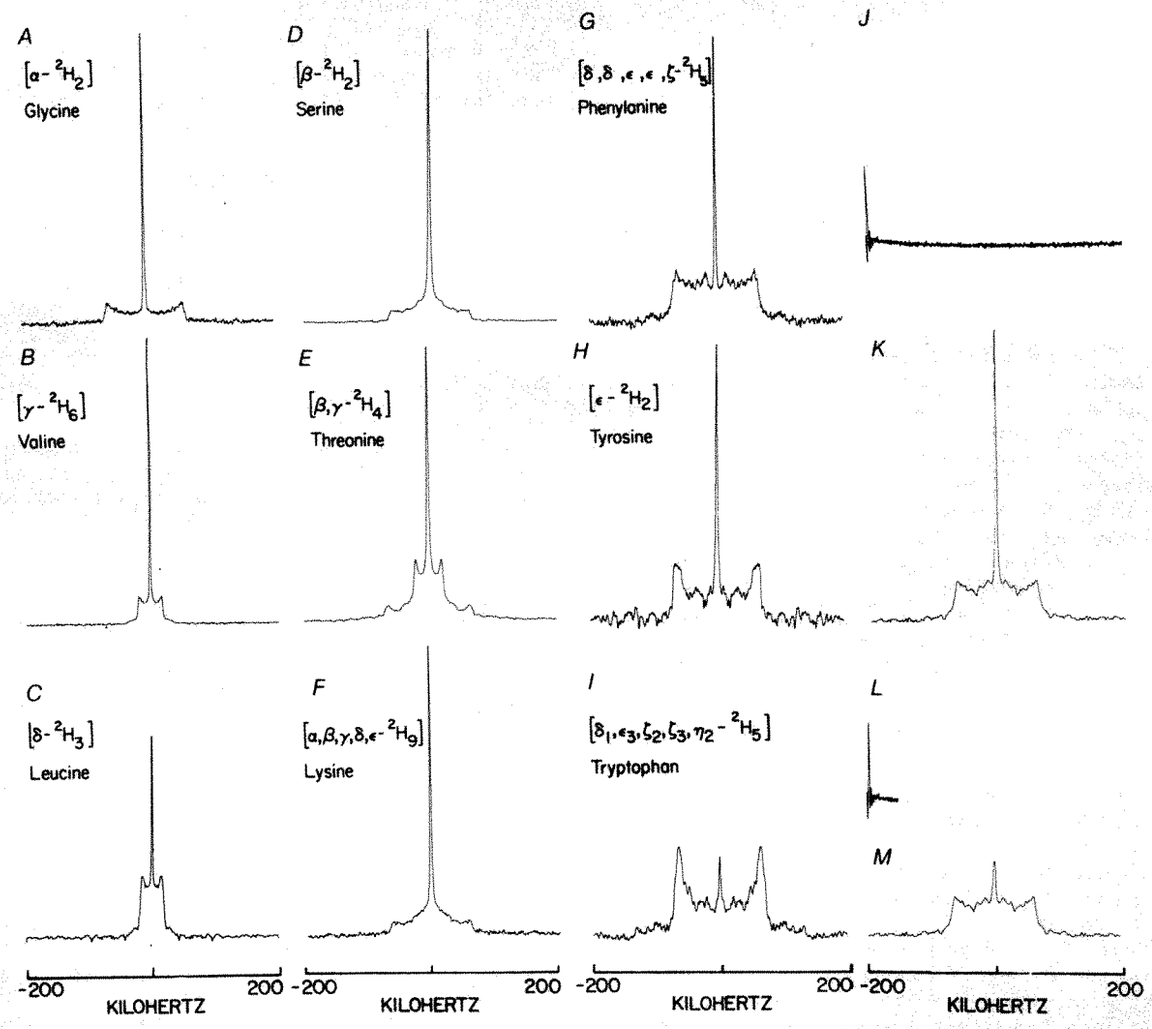

Fig. 1 Experimental ^2H NMR spectra (at 55.3 MHz and 4 °C) of selectively ^2H-labelled membranes, showing intensity of the central (surface) component, and truncation effects. *A–I*, ^2H-labelled amino acid, as indicated. *J–M*, [$^2H_5$]phenylalanine-labelled bacteriorhodopsin in the time and frequency domains. *J*, *K*, 4,096 data points, *L*, *M*, 512 data points. Note that inadequate digitization causes a loss of central-component intensity. The spectra were obtained on a home-built instrument which consists of a 3.5-inch bore 8.45 Tesla superconducting solenoid (Oxford Instruments), a Nicolet 1180 computer interfaced to a Nicolet NIC-2090 50-ns transient recorder system (Nicolet), and a variety of digital and radiofrequency electronices[10]. Spectra were recorded for a 800-μl sample, with a quadrupole-echo pulse sequence[11] using a 90° pulse width of ~3 μs. The spectrometer was prepared for data acquisition as described previously[12]. DL[β-$^2H_4$]serine was synthesized from ethyl acetamidocyano-acetate by reduction with sodium borodeuteride, followed by hydrolysis with strong acid[13] and recrystallization from aqueous ethanol. DL[β, γ-$^2H_4$]threonine (~75% in the *threo* form) was synthesized by condensing [$^2H_4$]acetaldehyde (Merck, Sharpe and Dohme) with *bis*-glycine copper (II)[14]. Copper was removed on a column of Dowex 50W-X8 (Bio-Rad) with 5M NH_4OH as the eluant. After removal of the solvent under reduced pressure, the DL[β, γ-$^2H_4$]threonine was recrystallized from methanol/water (4: 1, v/v). [α-$^2H_2$]glycine, L[δ-$^2H_3$]leucine, and DL[α, β, γ, δ, ε-$^2H_9$]lysine were purchased from Merck, Sharpe and Dohme, and L[α, β, γ, δ, ε-$^2H_{10}$] isoleucine was from Cambridge Isotopes. DL[γ-$^2H_6$]valine, L[δ_1, δ_2, ε_1, ε_2, ζ-$^2H_5$]phenylalanine, L[ε_1, ε_2-$^2H_2$]tyrosine and L[δ_1, ε_3, ζ_2, ζ_3, η_2-$^2H_5$]tryptophan were prepared as described previously (refs 15, 16 and references cited therein). *Halobacterium halobium* R_1 (the kind gift of Professor T. Ebrey) was grown and harvested as described previously[15,16]. Deuterated amino acids were incorporated into a defined medium at the following concentrations: [$^2H_2$]Gly, 0.6 g per 10l; DL[γ-$^2H_6$]Val, 10.0 g per 10l; L[δ-$^2H_3$]Leu, 0.2 g per 5l; L[α, β, γ, δ, ε-$^2H_{10}$]Ileu, 0.2 g per 5l; DL[β-$^2H_2$] Ser, 3.0 g per 10l; DL[β, γ-$^2H_4$]Thr, 5.0 g per 10l; L[α, β, γ, δ, ε-$^2H_9$]Lys, 0.2 g per l; L[δ_1, δ_2, ε_1, ε_2, ζ-$^2H_5$]Phe, 1.3 g per 10l; L[ε_1, ε_2-$^2H_2$]Tyr, 2.5 g per 10l; L[δ_1, ε_2, ζ_2, ζ_3, η_2-$^2H_5$]Trp, 5.0 g per 10l. We have assumed that only L-amino acids were incorporated when DL mixtures were added to the growth medium. Purple membranes were isolated essentially by the method of Becher and Cassim[17], as described previously[15,16]. Membranes were exchanged three times with ^2H-depleted water (Aldrich) prior to NMR spectroscopy, by equilibrating in the H_2O (unbuffered and salt free) for 1 h at 23 °C, followed by centrifugation at 130,000*g* for ~14 h. Amino acid incorporation was checked in radiotracer experiments with 50 μCi of uniformly [^{14}C]-labelled amino acids per 500ml growth medium as described previously[15,16]. Val, Leu, Ileu, Thr, Lys, Phe, Tyr and Trp showed essentially no (≤5%) breakdown and reincorporation into other amino acids. However, only 52% of the ^{14}C-Ser counts in the purple membrane hydrolysate were found to be associated with that amino acid, the other radioactivity being associated with glycine (16%), alanine (12%) and tryptophan (9%). Similarly, only 81% of the ^{14}C-Gly counts were associated with glycine, the other radioactivity being incorporated into tyrosine (12%) and serine (6%). The amounts of endogenous amino-acid synthesis were not determined.

We also show in Fig. 3*F* the correlation between the per cent residues on the surface of a typical globular protein (the Wertz-Scheraga scale)[9], and the per cent isotropic component. This shows an even poorer agreement ($m = 0.98$, $c = 17.5$, $\rho = 0.61$), illustrating we believe the large differences between the membrane protein bacteriorhodopsin and a typical globular protein.

Finally, we note that the ^2H NMR spectra of highly aggregated purple membrane sheets (obtained by mild tryptic cleavage of the C-terminal residues) do not exhibit the intense central components characteristic of mobile surface residues. For example, in the case of [γ-$^2H_6$]valine, the central component contributes 35% to the intensity of the untreated membrane

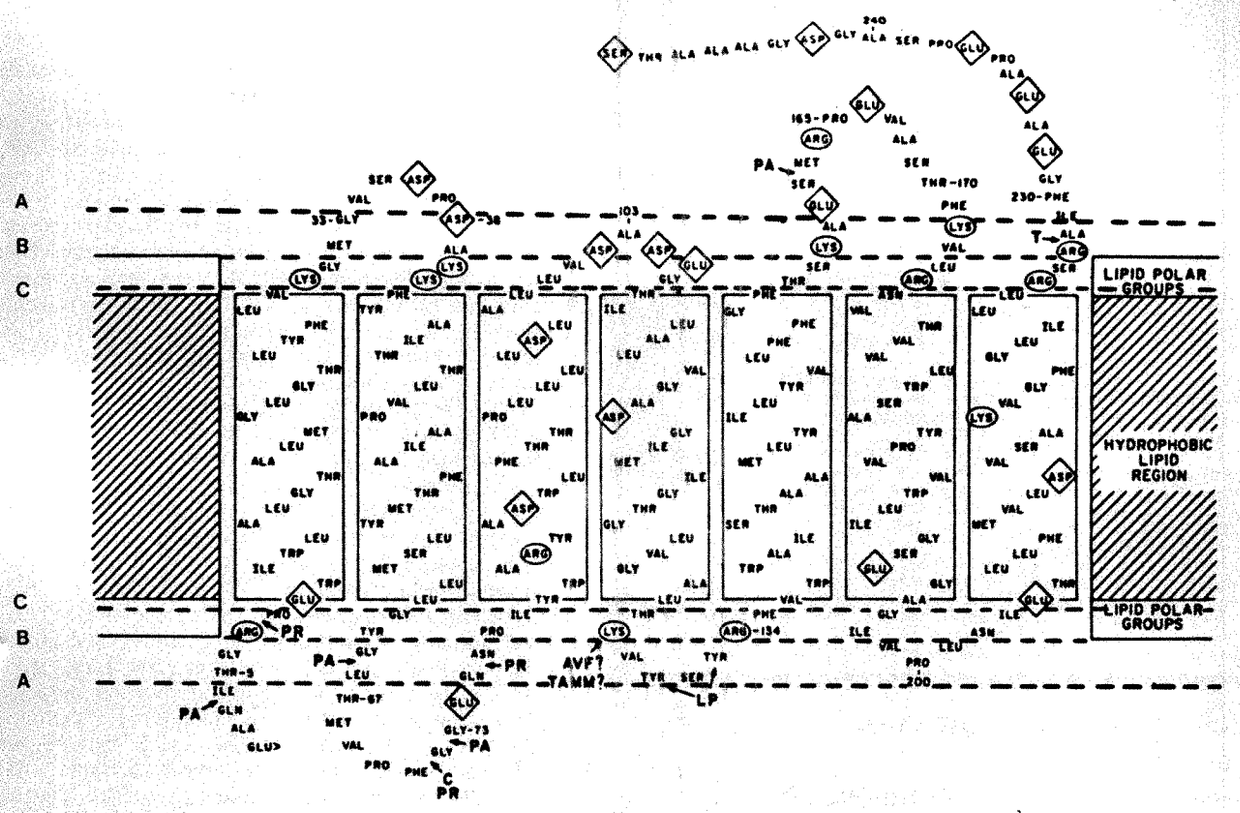

Fig. 2 Proposed model of secondary structure of bacteriorhodopsin (ref. 4) showing various definitions of the membrane surfaces (A, B and C).

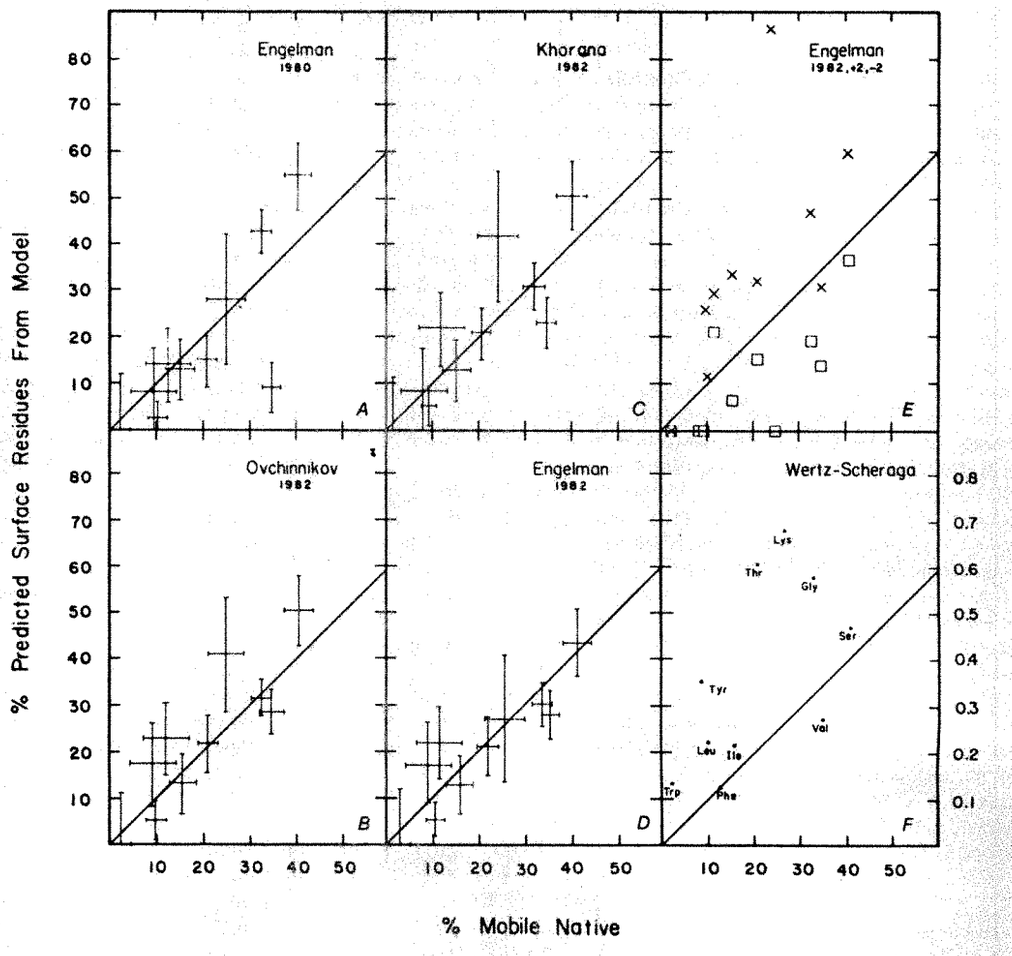

Fig. 3 Correlations between per cent surface residues for various theoretical models of bacteriorhodopsin structure, and per cent isotropic component in the ^2H NMR spectrum (Fig. 2). *A*, Engelman, 1980 model. *B*, Ovchinnikov, 1982 model[2]. *C*, Khorana, 1982 model[3]. *D*, Engelman, 1982 model[4]. *E*, Engelman, 1982 model using as surface definitions lines *A* (+2, □) and *C* (−2, ×) from Fig. 2. *F*, Correlations with the Wertz-Scheraga index[9]. The vertical error bars are percentage errors for an error of ± one residue. The horizontal error bars represent an estimate of the experimental error in the central component intensity determination. The straight lines in each part are the theoretical relationship ($m=1$, $c=0$).

spectrum but only 7% to the intensity of the spectrum of the membrane after digestion, even though no valines are removed (unpublished results). This suggests that the motional states of membrane surface residues are highly sensitive to the nature of the surroundings, and such dynamic interactions could have a role in processes such as cell–cell recognition.

Preferential integration of yeast transposable element Ty into a promoter region

Hermann Eibel* & Peter Philippsen†

Microbiology Department, Biozentrum, University of Basel, Klingelbergstrasse 70, CH-4056 Basel, Switzerland

Mobile genetic elements have been identified in several eukaryotic organisms and some classes have been found to share common structural features with the proviral forms of animal retroviruses[1–7]. The representatives of this class of mobile elements in the yeast *Saccharomyces cerevisiae* are called Ty elements[8], which could be a useful model system for studying the transposition of retrovirus-like elements. Here we have attempted to answer two questions often raised in discussions of the biological importance of transposition: what is the frequency of spontaneous Ty transposition, and are there certain chromosomal regions into which Ty elements preferentially integrate? We chose the *LYS2* gene to investigate these questions because it allows direct selection of both mutants and revertants[9]. We have found that 2% of spontaneous lys2 mutants are caused by Ty transposition with a preferential integration into the transcription initiation region.

303 mutant strains with no (lys2) or significantly reduced (lys2aau) expression of the *LYS2* gene were isolated from two haploid *S. cerevisiae* strains as described in Fig. 1 legend. Both strains carried about 35 Ty elements[2,8]. Total DNA from groups of five or six of these mutants was cleaved with the restriction nucleases *Xho*I or *Xho*I plus *Bgl*II. These minipools were screened by DNA hybridizations[10] for size alterations in the wild-type *LYS2* restriction fragments using the cloned *LYS2* gene[11] as probe (Fig. 1*a*). Non-wild-type hybridization signals were observed within five minipools, and examples are documented in Fig. 1*b*. Rescreening of the individual strains in the five minipools identified in each case one mutant strain with altered *LYS2*-specific restriction fragments; three lys2 mutants (lys2–4, lys2–8, lys2–19) and two lys2aau mutants (lys2–17, lys2–655). Further analysis with *Bam*HI cleaved DNAs revealed in all cases an approximately 6-kilobase(kb) insertion as documented in Fig. 1*c*.

To identify the inserted sequences, we cloned and analysed at first the lys2–655 allele. After determining the sizes of restriction fragments which would cover part of the unaltered *LYS2* gene and part of the inserted DNA, we chose a 5.6-kb *Bam*HI–*Sal*I fragment for cloning into pBR322. The restriction map of this clone (pCH655) is shown in Fig. 2*a*, together with the restriction maps of Ty*1* and Ty*2*, the two known types of Ty elements[12,13]. A comparison clearly identifies the insertion in lys2–655 as a Ty*1* element. Furthermore, hybridization experiments against *Eco*RI-cleaved S288C DNA using pCH655 as probe revealed a typical Ty*1* pattern[8] (data not shown). Since the lys2–655 mutant could grow without lysine (lys2aau phenotype) it is not surprising that the Ty*1* had inserted in this mutant into the promoter region, as indicated in Fig. 2*a*, and not in the transcribed portion of the *LYS2* gene. The actual distance between the Ty*1* integration site and the start of the *LYS2* coding region is 107 base pairs (bp) as determined by DNA sequence analysis (D. Pridmore and P.P., unpublished).

The expression of the lys2–655 allele is only 20% of the wild-type level (H.E., M. Winston, J. K. Bhattacharjee and P.P., manuscript in preparation). We assume that the reduced transcription is still directed by *LYS2* promoter elements and not by δ promoter sequences in the Ty ends[3], as δ promoted transcription would proceed away from the *LYS2* gene as judged from the Ty*1* orientation in this insertion mutant.

The insertions in the other four mutants were identified by an extensive hybridization analysis using five restriction nucleases as Ty*1* elements in the three lys2 mutants lys2–4, lys2–8, lys2–19 and as a Ty*2* element in lys2–17, the second lys2aau mutant. Examples are documented in Fig. 2*b* and *c* for the *Xho*I and *Xho*I–*Bgl*II hybridization spectra, respectively. These five cases of Ty insertions were found among 303 spontaneous lys2 and lys2aau mutants. Such mutants occur with a frequency of 5×10^{-6} in haploid *S. cerevisiae* (ref. 9 and Fig. 1 legend). The spontaneous frequency of Ty transposition in these strains, which carry around 35 Ty elements[2,8], is therefore approximately 10^{-7}.

*Xho*I cleaves most Ty elements in their terminal δ sequences[12,13] and cleaves once within the *LYS2* gene[11]. *Xho*I-cleaved DNA from all five mutant strains showed a strong signal at around 3 kb (Fig. 2*b*). This indicates a clustering of the Ty insertion sites 3 kb upstream from the *LYS2 Xho*I site, a region which coincides with the *LYS2* promoter. A more precise localization of the Ty insertion sites was obtained with *Xho*I–*Bgl*II-co-digested DNA using the 650-bp *Bgl*II–*Eco*RI fragment as probe (see Fig. 1*a*), which contains the *LYS2* promoter. This probe detects only short restriction fragments (Fig. 2*c*). The sizes of these fragments minus the known distance between the Ty end and the δ *Xho*I site revealed the integration sites of the respective Ty elements. The result is presented in Fig. 3. Four of the five Ty insertions map within 40–110 bp in front of the *LYS2* translation start and one Ty maps 220 bp after this start.

This clustering around the start of the 4,000-bp long *LYS2* gene is remarkable, since any Ty insertion within the coding part of the gene would have been detected as a lys2 mutant in the selection procedure. As the α-aminoadipate-based selection for lys2 mutants allows the isolation of a great variety of lys2 mutants, including nonsense and missense mutations[14], its influence on the nonrandom distribution of Ty elements is highly improbable. In addition, insertion of DNA into the *LYS2* gene is not *a priori* impossible; for example, when *S. cerevisiae* cells are transformed with linear DNA harbouring *LYS2* sequences at both ends, an efficient insertion into the *LYS2* coding region is observed[11] resulting in a lys2$^-$ phenotype.

The target preference of Ty elements is therefore best explained as an intrinsic property of the elements, which enables Ty elements to discriminate between favourable targets and other less 'attractive' DNA sequences. This could be based on the ability of the Ty transposition machinery to recognize differ-

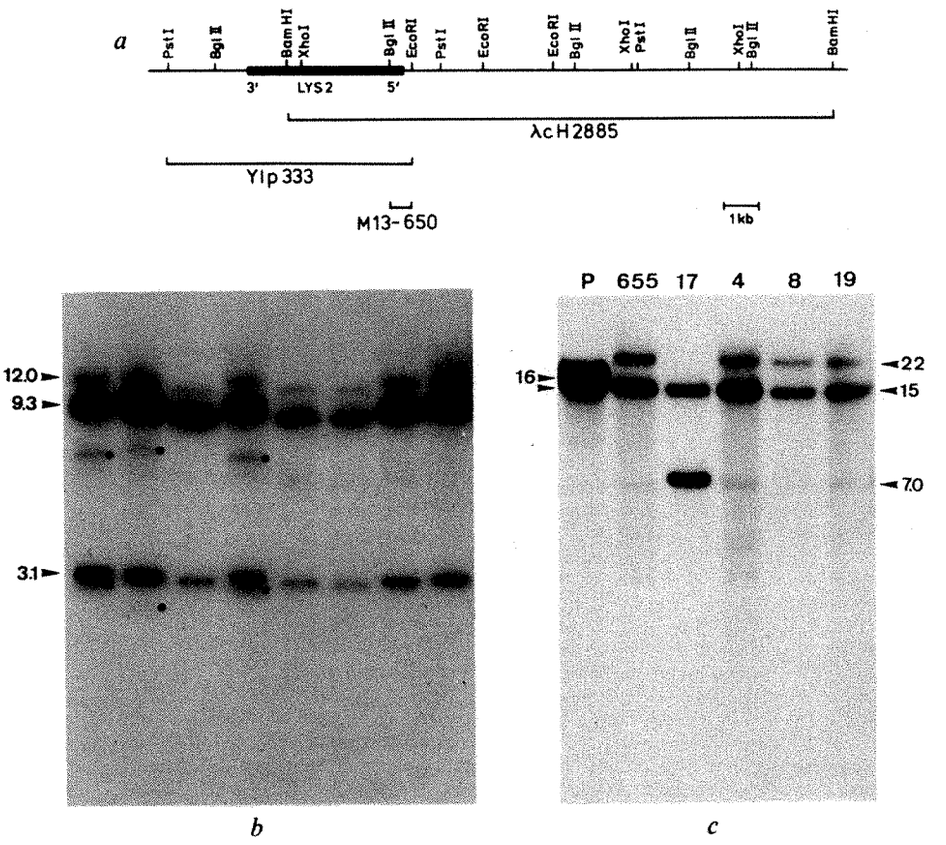

Fig. 1 Screening of lys2 mutants for DNA rearrangements. ***a***, Restriction map of the *LYS2* gene region in chromosome II from *S. cerevisiae*[11] and origin of *LYS2* probes. λCH2885 carries the 16-kb *Bam*HI fragment cloned into λ1059 and YIp333 carries the 6.9-kb *Pst*I–*Eco*RI fragment cloned into pBR322[11]. M13–650 carries the 650-bp *Bgl*II–*Eco*RI fragment of the *LYS2* promoter region cloned into the M13 vector mp8[33]. ***b***, Hybridization signals of *Xho*I restriction digests obtained with pools of mutant DNAs. Cleaved DNA was separated in 0.5% agarose and probed with λCH2885. The 9.3- and 3.1-kb signals correspond to internal *Xho*I fragments of the probe (see *a*); the 12-kb signal represents the *Xho*I fragment extending to the right of the probe. The *Xho*I fragment extending to the left of the probe is ~20 kb and was not transferred in most cases. New signals pointing to DNA rearrangements are marked in three of the eight lanes. Each lane contained a DNA mixture from six spontaneous lys2 mutants obtained from strain V2. ***c***, *LYS2*-specific *Bam*HI restriction fragments in parental and mutant strains. DNA of the parental strain S288C and the mutants lys2–655, lys2–17, lys2–4, lys2–8 and lys2–19 (from left to right) was cleaved with *Bam*HI, separated in 0.5% agarose and hybridized with YIp333. The parental DNA (lane P) exhibits the two expected signals of 15 and 16 kb, which correspond to the sequences extending to the left (3′) and right (5′) of the cleaved *Bam*HI site in the *LYS2* gene, respectively (see *a*). All mutant DNAs have lost the 5′-specific 16-kb signal and four show a 22-kb signal instead, indicating a 6-kb insertion. DNA from the mutant lys2–17 also carries a 6-kb insertion in the 16-kb fragment but one with a *Bam*HI site, leading to a 7- and a 15-kb signal. The latter one co-migrates in this case with the unchanged 15-kb fragment from the 3′ side, but its existence could be clearly demonstrated using λCH2885 as probe (not shown).

Methods: The selection for lys2 mutants is based on the use of α-aminoadipate as sole nitrogen source as described by Chattoo *et al.*[9]. 95% or more of *S. cerevisiae* cells which grow on α-aminoadipate plus lysine are lys2 mutants; among them are some with residual activity, called lys2aau mutants. We used the two haploid strains V2 (a trp1 his4) and S288C(α gal2 mal) as source for mutants. The frequency of spontaneous lys2 plus lys2aau mutants was in both cases 5×10^{-6} per cell, which is in agreement with previous work[9]. Cells from 60 single colonies of strain V2 were grown to stationary phase in full medium and 5×10^{7} cells each were plated on α-aminoadipate plus lysine. From each plate we collected only one lys2 and one lys2aau mutant in order to be sure to analyse independent mutation events. In total we collected 54 lys2 and 58 lys2aau mutants. A second set of mutants was derived from strain S288C. Cells were grown this time in minimal medium (lacking lysine) to the end of the logarithmic phase and plated at high densities on selective medium. After an incubation at 30 °C for 5 days, 196 mutant colonies were obtained. 176 of these mutants complemented a lys5 tester strain but not a lys2 tester strain and were classified as lys2. 15 of the mutants grew on selective medium but also on medium lacking lysine and complemented lys2 and lys5 mutations; they were classified as lys2aau. The remaining 5 mutants were lys5. DNAs were isolated as described previously[11]. Hybridization of the cleaved DNA after transfer to nitrocellulose was performed according to Southern[10] with the modifications introduced by Smith and Summers[34]. Nick translation[35] was used to label the hybridization probes. The lengths of the restriction fragments were determined from a comparison with co-migrating λ*Hin*dIII fragments[36].

ences in the chromatin structure of regulatory and coding sequences resulting in a higher affinity for opened regions. DNA sequence characteristics which would lead to such opened regions have not yet been elucidated. It has been noted previously that target regions for Ty transposition contain 60–80% A·T base pairs[15,16,20] in a genome with an average A·T content of 60%. The DNA sequence at the beginning of the *LYS2* gene shows one A+T-rich region (72%) centred around 70 bp in front of the translation start and another A+T-rich region (80%) centred around 240 bp after the start (D. Pridmore and P.P., unpublished). These locations coincide with the Ty integration sites.

Our data do not allow any conclusion as to whether the 3′-flanking regions of genes are also Ty landing sites, as such insertions would probably not be detected in the selection system used. In this context it is also important whether our observations made with Ty insertions at the *LYS2* locus are specific for that gene, or if similar events also occur at other loci in *S. cerevisiae*. Ty insertions have been observed in front of the *HIS4* (refs 16–18), *ADH2* (refs 19, 20), *CYC7* (refs 21, 22), *CAR1* (ref. 23) and *HIS3* (ref. 24) genes. The selection system used to recover these mutants would not have allowed the detection of Ty insertions into coding regions, except for *HIS4*, where two Ty insertions in front of the gene were characterized[16–18]. A conclusion as to the target specificity would have been difficult, if not impossible, from these studies. The nonbiased lys2 selection system with its potential for isolating many Ty insertion mutants therefore allows a thorough analysis of Ty transposition in yeast.

Several laboratories have recently found Ty elements or δ sequences close to the 5′ end of several tRNA genes (summarized in ref. 25). If δ sequences and tRNA genes were randomly distributed, they should be about 20–30 kb apart in the yeast genome. The close association found is therefore remarkable and may again reflect the attractiveness of regions 5′ to transcribed sequences as Ty landing sites.

Retrovirus-like mobile elements in higher eukaryotes were also frequently detected around promoter regions[26–32] and further studies may confirm a preference for such regions as integration sites. Thus insertions of these elements would frequently

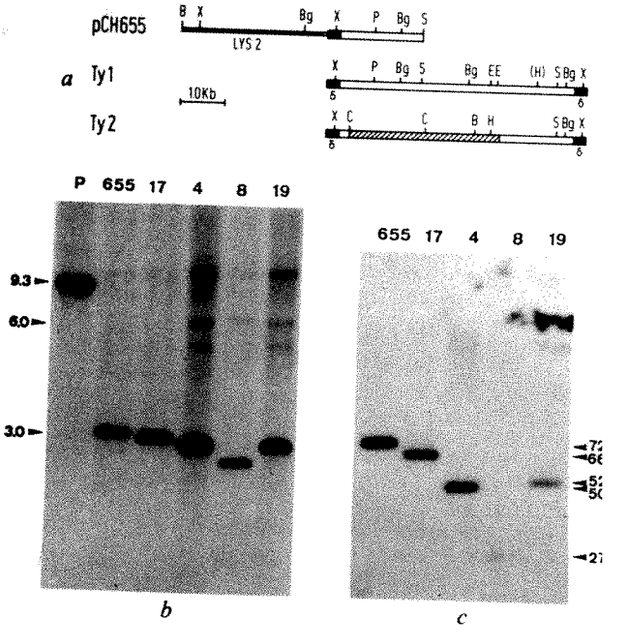

Fig. 2 Identification and mapping of Ty elements at the *LYS2* locus. *a*, Restriction map around the *LYS2*–Ty junction of the mutant lys2–655 as determined from the cloned 5.6-kb *Bam*HI–*Sal*I segment. The known restriction maps of Ty*1* and Ty*2*[12,13], which differ by a 3.5-kb substitution, are also shown. B, *Bam*HI; X, *Xho*I; Bg, *Bgl*II; P, *Pst*I; S, *Sal*I; E, *Eco*RI; H, *Hin*dIII; C, *Cla*I. The thin black line represents transcribed *LYS2* sequences[11]. Black boxes represent δ sequences, which are the 335-bp long terminal repeats in Ty elements[8,15,16]. *b*, Autoradiogram of *Xho*I restriction spectra from DNA of strain S288C and the five insertion mutants. The hybridization probe was nick-translated YIp333 which hybridizes in both parent strains to a 9.3-kb and a 20-kb *Xho*I fragment[11] (the latter did not transfer well). DNA of all mutant strains showed a new signal at around 3 kb. The corresponding new *Xho*I sites reside within the left δ sequences of the inserted Ty elements[15]. The *Xho*I fragment extending from the right δ sequences of the inserted Ty elements to the *Xho*I site upstream of the *LYS2* promoter can only be seen as weak signals in the 6–7-kb range due to the short homology with the probe. For orientation see Fig. 1*a*. The weak signals at around 5 and 10 kb are probably due to cross-hybridizing sequences elsewhere in the genome[11]. *c*, Autoradiogram of *Xho*I–*Bgl*II restriction spectra in 1.2% agarose from DNA of the five insertion mutants. The probe was M13–650, which carries the *LYS2* promoter (see Fig. 1*a*). The numbers at the arrows designate fragment sizes in base pairs which were determined from co-migrating pBR322 *Hpa*II fragments[37]. The size of 720 bp for the signal in lys2–655 DNA was independently determined from the pCH655 clone (see *a*) and was confirmed by DNA sequence analysis (D. Pridmore, personal communication).

Methods: The 5.6-kb *Bam*HI–*Sal*I fragment harbouring the *LYS2*–Ty*1* junction of the mutant lys2–655 was cloned into the plasmid vector pBR322[38] after an enrichment step. 10 μg of *Sal*I + *Bam*HI-cleaved lys2–655 DNA were electrophoresed on a 0.5% agarose gel and fragments of 5–7 kb electroeluted as described by Yang *et al.*[39]. The yeast DNA was ligated with *Sal*I + *Bam*HI-cleaved pBR322 DNA which had also been purified by electroelution. Ampicillin-resistant transformants in *Escherichia coli* were screened for the presence of the 5.6-kb *Sal*I–*Bam*HI fragment by colony hybridization[40] using YIp333 as a probe. Sheared and denatured unlabelled pBR322 was added in excess to suppress hybridization between the labelled pBR322 sequences in the YIp333 probe and pBR322 DNA present in the *E. coli* transformants. One of the positive clones was picked and shown to contain the right plasmid, which was named pCH655.

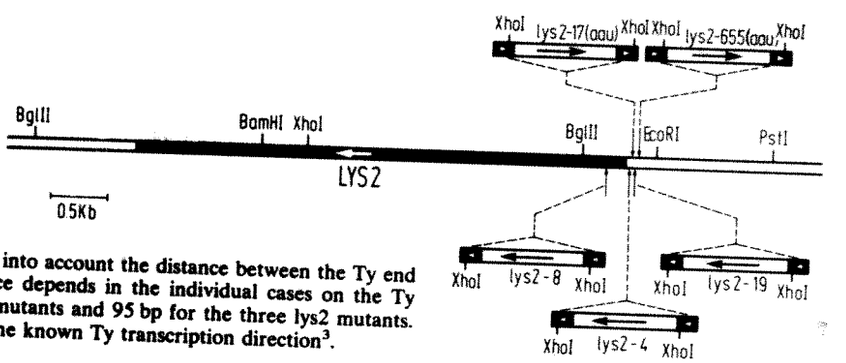

Fig. 3 Map of Ty insertion sites. The insertion sites of the five Ty elements in the transcription start region of *LYS2* are indicated by arrows. The 4-kb long *LYS2* gene is drawn as black bar. The 5′ end of this gene was determined from a DNA sequence analysis which identified the translation start (D. Pridmore and P.P., unpublished). The 3′ end was determined by several independent S_1 mapping experiments[11]. The 6-kb long Ty elements are not drawn to scale. Their insertion sites were calculated from the *Bgl*II–*Xho*I fragment sizes measured in Fig. 2*c* by taking into account the distance between the Ty end and the *Xho*I site in the δ sequence. This distance depends in the individual cases on the Ty orientation[15,16] and is 240 bp for the two lys2aau mutants and 95 bp for the three lys2 mutants. The arrows within the Ty elements correspond to the known Ty transcription direction[3].

lead to a modulation of gene expression rather than to gene inactivation. This could be a molecular basis for the often postulated role of mobile DNA elements in evolutionary processes.

We thank Ursula Fleig for the m13-650 clone, Agathe Stotz for technical assistance, also Lucia Panzeri, Jürg Gafner and David Pridmore for many stimulating discussions, Tom Bickle for critically reading the manuscript and Elvira Amstutz for typing it. This work was supported by Swiss National Fund grant 3.644.80 and by a fellowship to H.E. from the Deutsche Forschungsgemeinschaft.

Solution contact charging with respect to earthquake lights

LOCKNER *et al.*[1] have proposed a mechanism to explain the production of earthquake lights (EQLs) which strongly relies on the generation of electricity by the boiling of water in heated rocks in the shear zone. Using data from the original paper on saline charging[2] and spray electrification they explain the coronal origin of EQLs for magnitudes 6–7 but were unable to account for those of the Matsushiro swarm. More recent investigations of solution contact charging[3,4] have demonstrated that the charging mechanism is not as Blanchard originally speculated, that is, "mechanical pulverization of water" with charge values similar to those of spray electrification, but is a solid–solid contact mechanism. Whereas sprayed aqueous solution droplets carry charges of about 4×10^{-19} C, those from solution contact boiling are in the range 3×10^{-17} to 3×10^{-14} C (refs 4, 5). The charges of 10^{-7} C g^{-1} quoted from Blanchard related to saline solution undergoing transition boiling on a surface at approximately 350 °C. However, at temperatures cited by Lockner *et al.*, in excess of this, Leidenfrost boiling occurs to produce charges of 10^{-5} C g^{-1}. Although Leidenfrost boiling produces fewer droplets, each carries higher charge by factors of 3–5 above those on sprayed droplets.

I suggest that the higher values are more likely and may also account for the EQLs of the Matsushiro swarm, thereby bringing the latter within compass of the proposed mechanism. One further observation is that previous studies of electrification from boiling have been based on $NaCl_{aq}$. An extension of these investigations[6] has revealed that many aqueous solutions including samples of groundwaters will generate electricity by flash, transition and Leidenfrost boiling.

The more recent information would seem to strengthen the mechanism proposed for the production of EQLs though some modification is required in which spray electrification should be deleted where boiling is involved and the more suitable solution contact charging process substituted.

Carnivore social behaviour—does it need patches?

RECENTLY, Macdonald[1,2] presented an interesting model explaining the evolution of social behaviour in carnivores. Briefly, the model, called the resource dispersion hypothesis (RDH), is as follows. Important food for carnivores occurs in patches and food availability in these patches varies with, for example, weather and season. Frequently situations occur when only one of these patches yields the resources needed for the animals' maintenance. Such situations can occur during single nights or seasons. Hence, the carnivore has to include enough patches within its territory (see, for example, Fig. 1 of ref. 1) to reliably support its minimum needs in all such situations. Territory size and configuration is determined by "dispersion of transient patches of available prey (ephemeral from night to night, or shifting from one season to the next)"[1]. Group size, on the other hand, is positively correlated with the average patch quality (or quality of the least valuable patch, it is unclear which) (Fig. 1 of ref. 1).

Macdonald discusses predictions that are not necessarily borne out by the model, for example: "From the resource dispersion hypothesis one would not necessarily expect .... any relationship between group size and territory area, as the two are argued to be affected, largely independently, by the abundance and dispersion of available food respectively". The lack of such a correlation is then treated as a corroboration of the model[1]. However, as RDH cannot be falsified regardless of whether there is a correlation or not, this prediction is useless for testing the hypothesis. Here I will identify and evaluate one prediction that is an *invariable* consequence of RDH: when the temporal variation is such that access to a given patch is vital to the territory owners, then all group members are expected to exploit this patch simultaneously. If the group members *regularly* forage in different patches simultaneously then the basic assumption of ephemerally unique food patches falls and so does RDH. This point was stressed by Bradbury and Vehrencamp[3] when developing a model (very similar to RDH) to explain territory and group size in emballonurid bats. These authors[3] found that all members of a given group of bats foraged in a common patch at any time.

Does it happen regularly that group members of, for example, badgers or red foxes forage simultaneously in a common patch? Macdonald's suggestion[1] that it may be "on a bad night or a bad year" makes it difficult to evaluate this prediction. Individual badgers move and hunt solitarily inside a clan range[4] and individual foxes are in physical contact with one another for as little as 4 min each night[5]. Also, Macdonald[6] reported that dominant and subordinate red foxes in his study area outside Oxford generally foraged in different parts (and patches; Table 6 of ref. 6) of the group territory. Moreover, in the Revinge area in southern Sweden, breeding red foxes differed, in all seasons of the year, from their non-breeding group members in their use of hunting habitat[7]. Thus, on neither a nightly nor a seasonal basis do members of a given group seem to be restricted in their hunting to a given patch. It is not likely that a whole group should unite at a single food patch during a 'bad' year, unless one considers the entire territory as one patch, but then RDH is no longer valid. Macdonald[1] concludes that once group living in carnivores has evolved as an adaptation to resource dispersion then other benefits accruing from sociality *per se* (for example, cooperative hunting and defence of kills) further moulds the social organization in each population or species and that "the balance of these contemporary benefits is not necessarily the same as that which originally selected for group living". Unfortunately, this *ad hoc* argument makes every serious attempt to test RDH virtually impossible as each time data that would falsify the hypothesis are obtained, it could always be claimed that a particular population is no longer under the original selection pressure for sociality. Even so, this would not help either for the Oxford or for the Revinge red foxes, as both populations are believed to be at an early stage in the evolution of sociality[1,8].

Recently[8,9] I argued that permanently territorial altricial vertebrates that feed on an interannually fluctuating food resource, keep a constant territory size if the animals' lifespan is longer than the average time period of the food fluctuations. The animals' territory sizes will be so adjusted that they contain enough food for reproduction, or at least survival[10], during the bottle-neck years of food scarcity. The model predicts that as food abundance increases, the territory owners, for example the breeding pair, take advantage of this resource surplus by allowing their adult offspring to remain at home, thereby increasing the group size. When food abundance decreases the subordinate group members will be evicted from the territory by the breeding pair. Hence, in any given territory of, say, foxes or badgers, group size will be positively correlated with the annual food abundance whereas territory size will be constant from year to year. This model does not include any assumption about ephemeral prey patches. A simple field test to distinguish

0028-0836/84/040389—02$01.00
© 1984 Macmillan Journals Ltd

between this model and RDH would be to prevent (for example, by a fence) groups of badgers or foxes exploiting a given food patch within their territories. My model predicts that territory size will remain constant if the experiment is performed in territories having three or more group members whereas group size will decrease in proportion to the ratio P_p/P_t, where P_p = prey productivity of the enclosed patch, and P_t = prey productivity of the entire territory. It is only when this experiment is performed in territories occupied by a single pair that the territory owners will try to expand or abandon their territories. Macdonald's[1,2] model predicts that territory size will increase whereas group size may or may not remain constant (depending on the quality of the new food patch incorporated in the territory).

MACDONALD REPLIES—Although most easily visualized where only one patch is likely to be fruitful in each territory at a given time (refs 1 and 2; hence Fig. 1 in ref. 3), the resource dispersion hypothesis (RDH) does not require these conditions[4–8]. Rather, the hypothesis identifies conditions of resource dispersion where "the smallest home range with an economically defendable[9] configuration which will reliably support a pair of foxes (on a bad night or a bad year) may sometimes support additional foxes"[3].

In spatially patchy environments, convoluted territorial borders might encompass sufficient fragments of transient patches to yield food for only a pair of residents. RDH proposes that the defence of such ranges may not be economic[9] whereas a less convoluted configuration, perhaps including more resources, could be defendable. On this view, each territory may contain many patches, each being variously fruitful at any one time. Whether group members forage in a patch simultaneously, just as whether they travel and/or forage alone or together, will depend on the nature of the prey and on other selective pressures affecting their sociality[3].

I have suggested[8] that where prey were spatiotemporally uniform in their availability, there the smallest economically defendable range that could sustain a pair would not support additional adults (whether or not, and for how long, it would be advantageous to maintain territories larger than this minimum size would depend on such factors as the magnitude of pressure from intruders and the benefits of increasing group size). von Schantz's formulation concerns an intermediate case where, irrespective of its dispersion, prey is temporally variable. Again, the pattern of prey availability creates conditions where the minimum range which supports a pair (in a poor year) can sometimes support extra adults (in a rich year). The interannual mode[10,11] highlights the question of how social behaviour provides "a buffer to prevent spatial organization altering prematurely in response to ephemeral changes in food availability"[8]. von Schantz's[10] emphasis on the costs of territorial readjustment is compatible with my formulation.

Territory size and shape may sometimes be adapted to 'bottle-neck' periods in the abundance of available prey; it seems no less plausible (nor at variance with the data[4–8] to argue that they are sometimes further constrained by the dispersion of resources. von Schantz is mistaken in thinking that I treated independence of territory and group sizes as corroborating RDH; rather, I showed how this was accommodated by RDH. Experiments like that suggested are vital although the result would depend on which patch was fenced (due to interacting variation among dominance and patch richness and utilization[12]).

von Schantz's hypothesis requires group size to descend to two during the average breeding lifespan. Among species which form "spatial groups"[3], these conditions are probably not met in some carnivore populations[13], although they may be in others[6,10]. The spatiotemporal formulation of RDH is applicable to groups of stable or unstable membership whereas the purely temporal formulation may explain only those unstable groups whose membership periodically decreases to two. Some badger and fox groups reported in refs 4, 5, 8 and 13 have subsequently remained larger than 2 for over 10 yrs (H. Hofer, D. W. M., E. Neal and J. Phillipson, unpublished observations).

111-day periodicity of X-ray transient A0535+26

PRIEDHORSKY AND TERRELL have recently argued about some special characteristics of X-ray transient A0535+26 (ref. 1) to justify their speculations: that (1) the optical counterpart HDE245770 of A0535+26 cannot be a BO Ve star; (2) it would be better if the terminal velocity of the stellar wind from HDE245770 were $<1{,}000$ km s^{-1}; (3) the B star must be rotating rapidly to lose matter from the equatorial region; (4) the companion HDE245770 must have a mass loss rate of $\sim 10^{-5}\ M_0\ \mathrm{yr}^{-1}$ to power the X-ray luminosity of A0535+26.

Furthermore, they point out that there is a discrepancy between evaluations of the mass loss rate from UV data and their own estimates (see point (4)).

These five points have been discussed elsewhere. Specifically: (1) HDE 245770, optical counterpart of A0535+26 (ref. 2), is an 0.9 IIIe star[3]; (2) the terminal velocity of the stellar wind in HDE245770 is ~ 630 km s^{-1} (ref. 4); (3) from the broadening of He(II) line (1,640 Å), the rotational velocity of HDE245770 is $v_e \sin i \cong 230$ km s^{-1} (ref. 5); (4) the mass loss rate of HDE245770, derived by IR data, is of the order of $10^{-6}\ M\ \mathrm{yr}^{-1}$ (ref. 6); (5) the discrepancy between evaluations of the mass loss rate derived from UV and IR data has been discussed in refs 5,7.

PRIEDHORSKY AND TERRELL REPLY—We thank Giovannelli for pointing out references relevant to our letter, some of which we may have overlooked even if space had permitted their inclusion. We had intended only to present new X-ray observations of A0535+26. It is satisfying that the IR studies cited by Giovannelli support our conclusion that the mean mass loss rate of HDE245770 to its companion A0535+26 is of the order $M \sim 10^{-5.5}$ $(v_{\mathrm{wind}}/1{,}000\ \mathrm{km\ s^{-1}})^4 \mathrm{M}_\odot\ \mathrm{yr}^{-1}$.

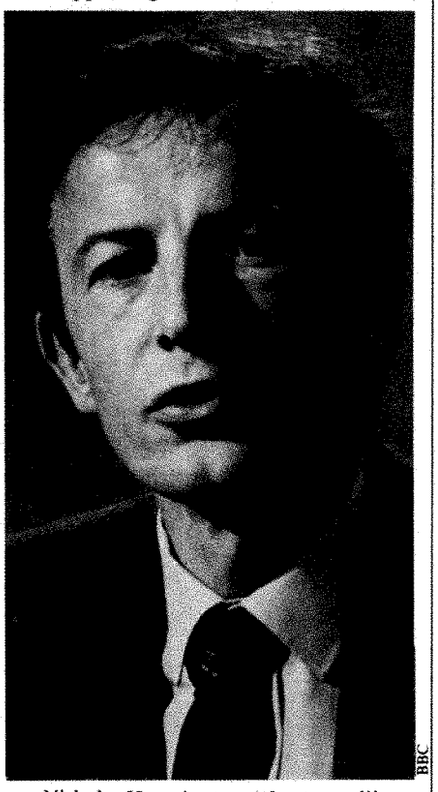
Consciousness and conscience



Stuart Sutherland

Consciousness Regained. By Nicholas Humphrey.
Oxford University Press: 1983. Pp.222. £12.95, $19.95.

MANY of the world's best minds have wrestled with the problem of consciousness; so for that matter have many of the worst. In *Consciousness Regained,* a collection of essays most of which have been published elsewhere, Dr Nicholas Humphrey joins the throng. He claims, unexceptionally, that since consciousness has presumably evolved, it must have a function, which is, he suggests, to enhance social interaction. He reaches this conclusion in two steps, the first of which concerns the intellect rather than consciousness.

According to Humphrey, the intellect in man and many other primates has been developed to a point far beyond that needed to deal with the material environment. He argues that chimpanzees and gorillas, who have invented a technology for subsisting, have less need for intelligence than do less technologically orientated primates. Merely by watching another member of its group, a chimpanzee can learn to poke a stick into a termites' nest and draw it out covered with a tasty feast. The individual animal does not have to use creative intelligence. The argument ignores the question of how the technique was invented in the first place: even if it was learned by trial and error, poking sticks into nests is a creative act and the chimpanzee has to make the connection between it and the resulting mouthful of termites. Moreover, although high intelligence might not be needed for day-to-day living, chimpanzees and gorillas must sometimes be subjected to novel and dangerous events which they can survive only by the use of intelligence. In the case of man, the argument is even weaker since his physical defences and resources are less and his survival — often under very adverse external conditions — depends entirely on his ability to manipulate the physical world by the use of intelligence. Although it is impossible to assess how far the intelligence of a given species evolved through pressure to cope with the physical world, there may be some truth in Humphrey's ingenious alternative — that in man and some other primates it evolved in order to help the individual deal with other members of the species.

There is, however, a big leap from this conclusion to the next step in his argument: he maintains that consciousness itself arose in order to help man (and possibly some other primates) understand the behaviour of others. Consciousness provides a model of the way in which people's own minds work — a model of their emotions, motives, thoughts and sensations: in so far as different minds are similar this model provides a basis for understanding others. There is, unfortunately, an obvious fallacy in the argument. The brain could represent the processes underlying motives, thinking and so on and could use this representation as a model for others' behaviour and the forces underlying it without the representation appearing in consciousness. Indeed,

Nicholas Humphrey — "fun to read".

Humphrey himself argues elsewhere that the brain contains a representation of the position of the parts of the body, but that this representation does not appear in consciousness. It is easy to invent functions that consciousness might subserve: what is difficult and has never yet been achieved is to show that they can be subserved only by consciousness.

There are three lesser problems with Humphrey's thesis. First, he does not sufficiently distinguish between consciousness and self-awareness. It is hard to believe that species other than primates lack consciousness, though they may lack self-awareness. Second, it is simply not true that in most of their dealings with others people use a conscious model either of their own behaviour or of that of others. People normally interact spontaneously and with little or no conscious thought. It is only when social interactions go wrong that they start to think consciously about them — often with unfortunate consequences. Third, if the reason why people are self-aware is to enable them to understand others, it is curious that self-knowledge should be so fallible. People's motives are often more transparent to others than to themselves.

For the rest, Humphrey is always stimulating and fun to read, though by its nature most of his book is rather bitty. He develops the far from novel idea that the reason why people engage in activities which seem to have no direct relevance to survival is that the activities provide novel experiences in terms of which people can better understand others. Some examples are play, initiation ceremonies, dreaming, keeping pets, watching dramatic performances and the manipulation of children by parents — particularly gratuitous cruelty. It is hard to accept that the function of such cruelty is to teach a child what it feels like to be unfairly treated, particularly as what evidence there is suggests that maltreated children tend to become poorly adjusted adults.

Another perennial problem that Humphrey tackles is that of the value of art. He argues that in classifying objects in the natural world, people look for sets whose members are similar in some respect to all the others, but differ in some way from the members of other sets. Much art (and, he might have added, almost all music) consists of variations on a theme and hence it teaches the viewer to spot similarities and differences and gives him practice in the task of classification. This is an ingenious account of the intellectual content of art, but leaves out its emotional force.

The book ends with a series of disconnected essays and book reviews, which are lively, but lightweight. Humphrey rightly and suavely demolishes the pretensions of such self-appointed gurus as Douglas Hofstadter and Gregory Bateson, and he provides a piece of impassioned rhetoric on nuclear war, in which he appeals to everyone to go out and stop it. He declaims "I have not heard of one good reason for not halting [nuclear armaments] tomorrow". Unfortunately he is so carried away by his own rhetoric that he omits to tell both the man in the street and the politicians exactly what it is they should do to prevent nuclear war.

Humphrey writes with elegance and force, and although he sometimes fails to follow his ideas through, they are always stimulating. Even the reader who disagrees with his arguments will derive pleasure from working out for himself why they are wrong. □

Stuart Sutherland is Director of the Centre for Research on Perception and Cognition at the University of Sussex.

Tackling the supreme symmetry

M. J. Duff

Superspace or One Thousand and One Lessons in Supersymmetry.
By S.J. Gates Jr, M.T. Grisaru, M. Roček and W. Siegel.
Benjamin/Cummings: 1983. Pp.548. Hbk $48, £40.80; pbk $25, £21.25.

HAD Scheherazade tried to while away those Arabian nights with *One Thousand and One Lessons in Supersymmetry*, one has the feeling that long before the chapter on quantum superspace Schahriar would have cried "Hey, wait a minute! Where are the references?". The graduate student of theoretical physics or other inquisitive researcher, hoping to use this text as a guide to the literature on supersymmetry and supergravity, will be sadly disappointed. Not one reference to the original works is to be found in the book. And of the six references to conference proceedings, one is incorrect. (The title of the 1981 Trieste proceedings should be *Supergravity 81* and the editors were S. Ferrara and J. G. Taylor.) The authors, all of whom are well-known Sultans of Supersymmetry, apologize to their friends in the field and beg pardon for omitting the credits. While I suspect that no such pardon will be forthcoming, this is nevertheless a valuable addition to the introductory literature on the ideas of supersymmetry and superspace which will be essential reading for the devotee.

In the words of the Introduction, "Supersymmetry is the supreme symmetry: It unifies spacetime symmetries with internal symmetries, fermions with bosons, and (local supersymmetry) gravity with matter". About one-third of the current publications in theoretical elementary particle physics is devoted to supersymmetry or supergravity, and an increasing number of experimental papers deal with the search for the still unobserved (and perhaps unobservable) superparticles which the theory predicts. More and more PhD students are choosing this field for their research yet constantly one hears the complaint that there is no adequate starting point for the learner. *Superspace* will certainly be of help, but it is not for the casual browser or the dilettante.

Supersymmetry experts fall into two categories: those who treat the theory like any other quantum field theory, using separate "component" fields to describe both bosonic (integer spin) and fermionic (odd-half-integer spin) particles; and those who prefer the new-fangled approach in which bosons and fermions are combined into "superfields" which live in a strange world called "superspace". In superspace, the four spacetime dimensions are bosonic with coordinates obeying the usual multiplication $AB = +BA$ but extra fermionic dimensions are also introduced whose coordinates obey $AB = -BA$.

As their title suggests, the authors of *Superspace* are unashamedly in favour of these superfields and use the superspace formalism throughout. They have covered all aspects of superspace: superspace geometry, representations of supersymmetry, and global superfields, but their ultimate goal is the unification of gravity and matter via supergravity. At present supergravity is the best available candidate for the Unified Field Theory which will unite gravity with the other fundamental forces of nature. One of the problems in such a scheme is to avoid the ultraviolet divergences of quantum gravity. The authors present a convincing case that only with the techniques of super-Feynman diagrams (for which they themselves have been largely responsible) can we hope to answer this all-important question.

Superspace is an Aladdin's cave of highly-condensed information. But although it is written with an easy style and admirable clarity, it will require a keen mind and determination, rather than a simple "Open, Sesame", to extract the riches. □

Michael Duff is a Lecturer in Physics at Imperial College, University of London.

Jenner by himself

Donald R. Hopkins

Letters of Edward Jenner: And Other Documents Concerning the Early History of Vaccination.
Edited by Genevieve Miller.
Johns Hopkins University Press: 1983. Pp.145. $15, £12.75.

THE recent global triumph over smallpox has stimulated great interest in historical aspects of that disease and persons associated with it. So it is the right time finally to have published these letters of Edward Jenner from the Henry Barton Jacobs Collection at Johns Hopkins University. More than anyone else, it was Jenner who set the stage for the eventual eradication of smallpox with his epochal discovery of vaccination in 1796.

Because of Jenner's great historical importance and his broad interests, I have often wished I could hear him describe his discovery and the related events that followed, at first-hand, or at least in a taped interview. Fortunately, even though Jenner is of an earlier era and we have no taped interview, we do have many of his letters, some 600 of which are known to still exist. This book contains a good many (110) of them, most being published here for the first time.

As Genevieve Miller notes in her brief introductory essay, in these letters to 45 different correspondents we meet Jenner the naturalist, author, father, country gentleman, scientist, husband, horticulturalist, geologist and the medical practitioner. We also meet a man who, like all of us, was occasionally wildly mistaken. Most interestingly, however, since all but two of these letters are from the period after he discovered vaccination (when he was 47 years old and already had made several significant scientific discoveries

Cow pock and the fears of the public — Gillray's celebrated cartoon of 1802, lampooning the activities of the Anti-Vaccine Society.

which were overshadowed by his later work), we meet the humanist Father of Vaccination. From 1796, until his death in 1823, Jenner constantly and doggedly promoted his discovery in the face of persistent opposition.

Some of these encounters seem to me to have almost as much force as if they were face to face. We feel Jenner's exaltation, for example, when he learns of the successes of vaccination in Copenhagen and Ceylon, and of the spectacular expedition dispatched by the King of Spain under Francisco Xavier Balmis which brought vaccination to Spanish territories around the world:

> A few days since, I rec'd from Madrid a Document respecting Vaccination which fills me with more astonishment than anything that has yet reach'd me on that subject . . . . Would to Heaven the British Cabinet had shown the same Philanthropic Spirit as that of Spain! [p.31].

We also share his exasperation and frustration at the cost in lives and suffering as a result of the antivaccinists in his own country, while much of the rest of the world adopted his discovery with thankful alacrity:

> One would think the statement of Facts, as they now stand before the Public from every quarter of the Globe would blow away such stuff as these abominable people produce, like Chaff, but it is not so, or the Bills of Mortality would not exhibit weekly such horrid scenes of devastation from the Smallpox [p.70].

No biographer or historian could convey Jenner's feelings during this period of his life better than he does himself in these letters.

The format of the book is well chosen. The annotated letters are presented in chronological order, except for the six which are of unknown date. Miller introduces the correspondents, and other persons as they are first mentioned, with short biographical sketches. In helpful but unobtrusive footnotes, she also explains various phrases, objects, practices and so on which are unfamiliar to us. Easy access to the contents is assured by means of an index, and by the table of contents in which Miller lists the letters in order, with the name of the correspondent and the key subject(s) discussed in each.

Fifteen other documents which are included in the 20-page appendix, we are told, "constitute the remainder of the unpublished Jacobs material relating to Jenner or to contemporaries involved with vaccination" (p.xxvi).

My only real disappointment after reading the book is a direct result of its effectiveness: I came away yearning to see all of Jenner's letters compiled and published in a single work. Until then, however, this collection will do very well. □

Donald Hopkins is Assistant Director for International Health at the Centers for Disease Control, Atlanta, Georgia. He is author of Princes and Peasants: Smallpox in History *(University of Chicago Press, 1983).*

All of physics

R.H. Dalitz

McGraw-Hill Encyclopedia of Physics.
Editor-in-chief Sybil P. Parker.
McGraw-Hill: 1983.
Pp.1,337. $59.50, £43.75.

The McGraw-Hill Encyclopedia of Science and Technology is a well-known publication, unique in its coverage of all fields of science. It has been revised about every five years, the most recent edition being the fifth which was published in 1982 (for review see *Nature* **229**, 283; 1982). Its articles have developed over the years, so that they are now well pruned of excess material and unusually free from errors.

This *McGraw-Hill Encyclopedia of Physics* has been made up by selecting 760 articles dealing with aspects of physics and mathematics, taken from the 1982 edition of the larger work. About 40 per cent of these articles are quite short, occupying less than a column but with ample cross-reference to the longer pieces in which they find a natural place. About 12 per cent are more substantial, occupying more than 8 columns each. Some of these are much longer, for example *gas dynamics* (15 columns), *superconductivity* (17), *radioactivity* (35) and *ultrasonics* (15). To categorize the articles in this way is perhaps misleading, however, since some large topics have been broken up; thus for fluid flow we have *fluids* (4), *fluid dynamics* (1), *fluid flow* (9), *fluid flow principles* (2), *fluid mechanics* (3) and *fluid statics* (1), not to mention *hydrodynamics* (8), *turbulent flow* (5), *magnetohydrodynamics* (11) and *gas dynamics* (15). On the other hand, *particle accelerator*, amounting to 50 columns, is a single entry but has seven sections, each with a different author. Perhaps more of the shorter pieces could have been grouped together in this way, although this might have made them appear forbidding to inexperienced readers.

Many of the articles are excellent. Plasma physics and nuclear physics are particularly well-served, the accounts being quite up to date and clearly illustrated, but the areas of elementary particle physics and condensed matter are also very well covered, as are more traditional topics in articles such as *units of measurement, sound, molecular physics* and *gravitation*. The mathematical articles are compact but generally quite accessible. Their style varies considerably; for example *combinational theory, graph theory, statistics* and *trigonometry* are clear and readable whereas a few of them, while being excellent and authoritative, are rather technical for the average physicist, let alone a high-school student. All but the shortest pieces have an adequate bibliography, two to five sources being quoted, generally covering standard books on the subject as well as one or two recent review articles. The articles are well cross-referenced, often paragraph by paragraph, and at the end of the volume there is a detailed index.

The reader will generally start with the index, which will offer a possible article. In reading this, he will find cross-references to related articles. By proceeding systematically in this way, he will generally be led to what he needs. For example, I tried the term *eigenvalue*, for which there is no article. The index referred me to *quantum mechanics* and to *eigenfunction*, while the latter referred me to the former and to *non-relativistic quantum theory*, so I quickly reached my goal. However, it is possible for topics to slip through this overlapping net. For example, spontaneous decay of the proton, a central topic of current research, is not in the index. The article *proton* does not mention it. The index for proton lists *proton radioactivity* but this turns out to be nuclear decay by the spontaneous emission of a proton. After some looking around, I found the topic contained in the *baryon* article under the subheading *proton stability*, and in the *elementary particle* article under the subheading *grand unified theories*. Another example is cosmic radiation, although this subject may perhaps be considered more a part of geophysics or astrophysics. The index led me to *bremsstrahlung*, in which proton emission by cosmic ray particles is briefly mentioned. This article gives a cross-reference to *cosmic rays*, but there is no article of that title. The basic facts about cosmic rays really merit a place in this volume, since they have been historically of immense importance and still give the highest-energy nuclear collisions available for study.

It is natural to ask how this encyclopaedia compares with the *Encyclopedia of Physics* published by Addison-Wesley in 1981 (for review see *Nature* **290**, 657; 1981). The main difference is that the latter is really intended for other physicists, or at least for scientists in neighbouring fields, who seek enlightenment on a topic peripheral to their own area of expertise. It has fewer articles but they are longer, on average, and considerably more technical, with equations being used freely. However, it seems that many of the articles of the Addison-Wesley encyclopaedia were written not later than early 1977, so it is not up to date on topics in areas of rapid growth. The McGraw-Hill version would appear to be the most suitable available for the audience to which it is directed — high schools and colleges. But all concerned with mathematics, physics, chemistry or engineering will find much of interest to them in its pages, laid out in an attractive and easily digestible form. □

R.H. Dalitz is Royal Society Research Professor in Theoretical Physics at the University of Oxford.

The Left Hand of Creation: The Origin and Evolution of the Expanding Universe.
By John D. Barrow and Joseph Silk.
Basic Books/Heinemann: 1983. Pp. 256. $17.95, £9.95.

"THEORETICAL astrophysics is as exact a science as geometry", remarked the Oxford mathematician E. A. Milne in a paper in 1930. Milne's affirmation in the exactitude of astrophysics followed introductory remarks outlining the problem of radiative transfer through a spherical shell of gas. This introduction concluded with an outspoken defence of what Milne saw as one of the chief necessities for progress — namely, the need to simplify a complex problem into an analytically tractable set of conditions, in his case the simultaneous and self-consistent solution of radiative transfer through matter, including ionization and excitation. Milne confined his attention to "the simplest question that can be propounded". That is, the case of static grey material. Today those working in the field of radiative transfer are approaching the solution of non-LTE (local thermodynamic equilibrium), extended, relativistically expanding atmospheres. But no one working in the field would deny the truth of Milne's justification for a simpler approach in 1930. "Until we have fully and rigorously discussed the case of grey material we are unlikely to make useful progress with more complicated hypotheses."

It is salutary to reflect on the state of model atmosphere theory half-a-century ago in the context of developments within modern cosmology. In the past cosmology has all too frequently been dismissed as an insular, acroamatic subject; a science which, with only the one singular case open to investigation, was doomed to failure on the grounds of inadequate experimental verification. For after all, so the argument goes, how could Newton possibly have succeeded in his theory of gravitation with only the one instance of a single apple falling on his head as experimental proof? Amusing though the myth may be, it was the extensive studies of motion and dynamics for two thousand years, from Aristotle and Richard of Wallingford to Galileo and Newton himself, which permitted a precise theory of gravity to be formulated.

However to view cosmology as the study of one experiment of the Grand Designer is to mistake the vessel for the cargo it contains. Cosmology is not the science of one single aspect of the Universe. Rather it is all aspects, woven against the tapestry of time, space and the forces of nature. The attempt to understand the origin, development and ultimate fate of its constituents is no different in principle from the aim of chemistry to unravel the code of chemical bonding, or of molecular biology to tease out the molecular basis of life.

Barrow and Silk present this quest with wit and gusto. Confident and experienced guides, they conduct their readers around the great debates in contemporary cosmology. At issue are such questions as the origin of the lack of antimatter, the source of spatial fluctuations responsible for all present structure in the Universe, the quasi-supernatural, as they seem superficially, properties of the vacuum giving rise to the paradox of black hole evaporation, and the progressive decomposition of the cosmic soup as time is run backwards towards the Planck time when the Universe was 10^{-43} seconds old, complete symmetry held sway, and all forces were indistinguishable.

No new development in fundamental physics can take place today without its influence on the evolution of the Universe being tested. Increasingly cosmology, and the astronomical evidence at its core, plays a fruitful role as a guide to permissable physical theorizing, supplementing more orthodox laboratory experiment and verification. The resulting astrophysical theorems aim at an ultimate amalgamation of theory and observation which will account for the form and content of the Universe — a Universe seen as a necessary consequence of physical law, with only the most basic axioms as the starting point.

But do not turn to this book for proofs of those theorems. The excitement and challenge are captured, but the rigour is necessarily elsewhere. Just as for many young minds the bald statement of Pythagoras's theorem is the first step towards a clearer perception of the structure underlying the physical world, so this book is a primer to recent attempts at unification of the forces of nature, and the powerful patterns those attempts are creating in the science of astrophysics. □

Geoffrey Bath is a Research Fellow of Wolfson College, University of Oxford.

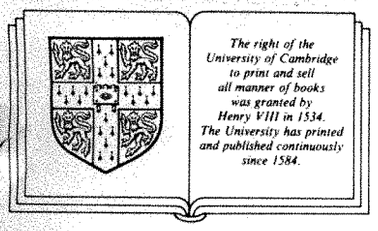
Fresh yeast

D.R. Harper

Yeasts: Characteristics and Identification.
By J.A. Barnett, R.W. Payne and D. Yarrow.
Cambridge University Press: 1983. Pp.811. £75, $150.

MANY of the outstanding publications dealing with the classification, nomenclature and identification of yeasts have, in the past, come from the Centraalbureau voor Schimmelcultures in Delft. Jacomina Lodder, of the Centraalbureau, edited what has for many years been considered as the definitive work on yeast taxonomy, *The Yeasts: A Taxonomic Study* (North-Holland, 1970), in which she provided the characteristics of 349 yeast species and described relevant laboratory methods. However, her scheme for identification placed emphasis on the ability of organisms to produce ascospores. This led, inevitably, to practical problems associated with demonstrating sporulation.

In England, J.A. Barnett and R.J. Pankhurst approached yeast identification in a different way, and in *A New Key to the Yeasts* (North-Holland, 1974) presented a computer-derived key which involved only physiological tests. *A New Key* was based on the information given in *The Yeasts* and was intended to be used in conjunction with it.



Five years later, *A Guide to Identifying and Classifying Yeasts* (Cambridge University Press, 1979) brought together as authors J.A. Barnett and R.W. Payne, with D. Yarrow from the Centraalbureau. Improved methods of computing were used to generate identification keys consisting of either physiological tests or both physiological and morphological observations. However, it was again necessary to consult Lodder's text for certain additional details.

The successor to *A New Key* and *A Guide* is *Yeasts: Characteristics and Identification*, an up-to-date book which does not rely on another work for any essential information. In it, Barnett, Payne and Yarrow discuss yeast classification and give commonly used procedures for yeast identification. In addition, they provide detailed accounts of 469 yeast species; responses to 83 tests and clear photomicrographs are also included.

The authors have revised the successful format of *A Guide* and incorporated it into this volume. They give 18 identification keys which deal with various groups of yeasts (for example, clinical isolates, yeasts associated with foods and beverages, and yeasts with particular physiological or morphological attributes). Lists of small numbers of tests for the identification of single species are provided. One chapter presents generic characteristics and another conveniently tabulates the characteristics of each species. The extra sections containing specific epithets and yeast names will undoubtedly prove invaluable given the confusion caused by nomenclatural changes in yeast taxonomy.

In producing this book, Barnett, Payne and Yarrow have met the daunting standards set by Lodder in 1970. *Yeasts: Characteristics and Identification* satisfies the requirements of being comprehensive and of containing easily accessible information. It will undoubtedly stand as *the* major text on yeast taxonomy for a considerable time to come. □

David Ross Harper is the microbiologist at the Metropolitan Police Forensic Science Laboratory, London.

CAMBRIDGE SCIENCE PUBLISHING

maintaining a great tradition

Reproduction in Mammals

Second Edition
Book 3: Hormonal Control of Reproduction
Edited by **C.R. AUSTIN** and **R.V. SHORT**

The latest volume in the thorough, updated revision of this classic work discusses the manifold ways in which hormones control the reproductive processes in both males and females.

0521256372 **Hard covers £22.50 net/ $39.95**
0521275946 **Paperback £8.95 net/ $16.95**

Animal Physiology

Adaptation and Environment
Third Edition
KNUT SCHMIDT-NIELSEN

The latest edition of this highly-praised, widely-used textbook has been completely revised and updated. In addition, new material on the brain and senses, and on nervous and endocrine functions is included.

0521259738 **£15.00 net/ $29.95**

Neural Origin of Rhythmic Movements

Edited by **A. ROBERTS** and **B.L. ROBERTS**

Thirty-seven contributors together provide a comprehensive and wide-ranging review of our basic knowledge of the way rhythmic movements originate within the nervous systems of both vertebrate and invertebrate animals.

Society for Experimental Biology Symposium 37

0521256348 **£37.50 net/ About $99.50**

The Physiology of Trematodes

Second Edition
J.D. SMYTH and D.W. HALTON

This detailed, revised account of our knowledge of one of the major groups of parasitic worms takes account of recent developments in our understanding of the ultrastructure, cytochemistry, biochemistry and immunology of the group.

0521222834 **Hard covers £30.00 net/ $59.50**
0521294347 **Paperback £11.95 net/ $23.95**

Progress in Anatomy, Volume 3

Edited by **V. NAVARATNAM** and **R.J. HARRISON**

This important review of recent research covers a variety of topics including primate evolution, quantification in microscopic studies, differentiation of the blastocyst, the intermediate lobe of the pituitary gland, primary sensory neurons mediating pain and prospects for regeneration in the mammalian central nervous system.

0521249538 **£37.50 net/ $74.50**

The Ecology of Phytoplankton

C.S. REYNOLDS

This comprehensive volume examines the life cycle of phytoplankton and considers the problems presented by a habitat without any solid surfaces: how can an organism stay buoyant in the water, gain sufficent nutrients and grow under difficult and diverse environmental conditions?

Cambridge Studies in Ecology

0521237823 **Hard covers £30.00 net/ About $49.50**
0521282225 **Paperback £12.50 net/ About $18.95**

Light and Photosynthesis in Aquatic Ecosystems

JOHN T. O. KIRK

In this unique general study, John Kirk examines in turn the physics of light transmission through water, the biochemistry and physiology of aquatic photosynthesis and the ecological relationships partly determined by the underwater light balance.

0521244501 **£37.50 net/ $74.50**

Eddington

The Most Distinguished Astrophysicist of His Time
S. CHANDRASEKHAR

A lucid non-technical account of the achievements of A.S. Eddington, for 31 years Plumian Professor of Astronomy at Cambridge during which time he made major contributions to astrophysics and general relativity.

0521257468 **£7.50 net/ $12.50**

Cecilia Payne-Gaposchkin

Her Autobiography and Other Writings
Edited by **KATHERINE HARAMUNDANIS**

The first woman professor and head of department at Harvard, Cecilia Payne-Gaposchkin can lay claim to be the greatest woman astronomer ever. This book traces her early life and academic career and is augmented by personal recollections of her daughter and historical appreciations from colleagues.

0521257522 **£19.50 net/ $34.50**

Ion-selective Electrodes

Second Edition
J. KORYTA and **K. STULIK**

This much-revised edition of a successful book presents a compact and unified treatment of the theory of ion-selective electrodes together with an updated account of their analytical, biomedical and physico-chemical applications.

0521238730 **£25.00 net/ $49.50**

Antarctic Earth Sciences

Proceedings of the Fourth International Symposium, Adelaide, 1982
Edited by **R. L. OLIVER**

Almost 100 scientists have contributed to this prestigious symposium which provides a comprehensive review of several seasons' research on all aspects of Antarctic earth sciences and Antarctic resources.

052125836 **£45.00 net/ $79.50**

Co-published with the Australian Academy of Science

Magnetic Oscillations in Metals

D. SHOENBERG

A systematic account of the nature of magnetic oscillation in metals, including descriptions of experimental techniques for the study of oscillations and the nature of their connection with the electronic structure of the metal concerned.

Cambridge Monographs on Physics

Diabetic Medicine

A Journal of the British Diabetic Association

EDITOR: Dr. John Ireland

Consultant Physician, Southern General Hospital, Glasgow G51 4TF, UK

EDITORIAL BOARD *will include*

K.G.M.M. ALBERTI	J.W. FARQUHAR	H. KEEN	R.B. TATTERSALL
D. ARMYTAGE	C.M. FLETCHER	JANET KINSON	J.D. WARD
A. BLOOM	C.N. HALES	P.H. SÖNKSEN	P.J. WATKINS

ASSOCIATE EDITORS

S.R. BLOOM	B.M. FRIER	R.J.JARRETT	W.M.G.TUNBRIDGE
J.L. DAY	E.A.M. GALE	SUE JUDD	S. WALFORD
C.J. FOX	D.R. HADDEN	J.I. MANN	P.H. WISE.

AIMS AND SCOPE

This journal is an information exchange on all aspects of diabetes mellitus and aims to interest everyone helping diabetic patients whether through fundamental research or better health care. The journal will provide a multi-disciplinary forum combining original articles, reviews, comment, news and corespondence by which it is hoped to increase knowledge about the aetiology and pathogenesis of diabetes and its complications and to promote new ideas about management and education.

EDITORIAL PHILOSOPHY

The aim of DIABETIC MEDICINE, as of the BDA itself, is to advance knowledge about diabetes and its management. DM should be of interest to those working in the centres of excellence, but the overwhelming need is to extend this interest to a wider audience and to generate a climate where diabetes will be identified as a subject deserving more health care resources.

AIMS AND SCOPE

THE JOURNAL OF PATHOLOGY is a journal of the Pathological Society of Great Britain and Ireland. From January 1984, it will incorporate the other affiliated journal, DIAGNOSTIC HISTOPATHOLOGY. The new group of Editors intend that the journal shall reflect the interests of the members of the Society. This will be no easy task since they cover the whole range of experimental and diagnostic histopathology.

High quality papers, written in English and dealing with descriptive histopathology will be welcome. Papers dealing with new techniques and those that elucidate the mechanisms underlying disease processes and histopathological appearance will be particularly encouraged.

Original articles in the field of experimental pathology, relevant to human disease, will be welcome. Review articles dealing with general and experimental pathology, as well as diagnostic histopathology, will be solicited. Unsolicited reviews will also be accepted if they are clearly written and topical. Editorials, a letter column and reviews of recently published books will form regular features of the Journal. Meetings abstracts of the Pathological Society of Great Britain and Ireland will be published as they become available and the annual C.L. Oakley Lecture will continue to be included.

FORTHCOMING ARTICLES

LIVER SINUSOIDAL CELLS by J.W.B. Bradfield

B_2 MICROGLOBULIN IN NON-MALIGNANT AND MALIGNANT HUMAN BREAST: A FEATURE OF DIFFERENTIATION by K. Sidky and R.A. Walker

Revised and updated edition

Photoelectron Spectroscopy

An introduction to ultraviolet photoelectron spectroscopy in the gas phase

J H D Eland, MA, DPhil,
Fellow of Worcester College, Oxford

When first published, *Photoelectron Spectroscopy* was praised by the *Journal of Electron Spectroscopy and Related Phenomena* as an "excellent treatise . . . a broad and lucid introduction suitable for chemists and physicists at advanced undergraduate and postgraduate level". It has now been carefully revised and updated for this new edition.

The purpose of the book remains unchanged; to provide the reader with a complete account of the subject at a practical level. The treatment is thorough but non-mathematical and the approach progressive, from a first familiarization with simple spectra through experimental methods and the photoionization process to the interpretation of ionization potentials and band shapes.

Hardcover 288 pages 215 × 138 mm

EXAMINE ON FREE APPROVAL WITHOUT COMMITMENT

TWO NEW reliable, up-to-date and complete biotechnology information resources.

Detailed information on every aspect of biotechnology worldwide

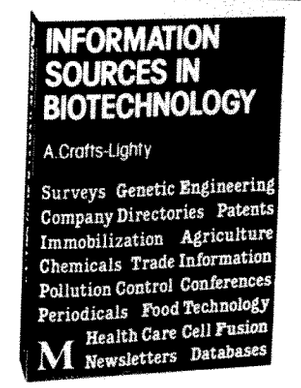
An indispensable guide to:
★ Products, services and research
★ Companies ★ Information sources.
★ Government and international agencies

THE INTERNATIONAL BIOTECHNOLOGY DIRECTORY 1984 —
- is thoroughly international
- features a unique BUYER'S GUIDE to products, research and services
- covers both the old and new biotechnologies

The Directory tells you:
★ Who your competition is, and what they are doing.
★ Who are potential customers and suppliers.
★ Where to buy equipment, chemicals and services.
★ Where culture collections are located and what cultures they hold.
★ Who imports/exports biotechnology products in over 20 countries.
★ Which government departments are associated with biotechnology.

All compiled by the eminent biotechnologist Dr. Jim Coombs and now available to you on **FREE APPROVAL.**

Macmillan Paperback 320pp **September 1983**
ISBN 0 333 36178 4 **£40.00/$80.00**



The ONLY guide to the selection of cost effective biotechnology information sources

★ covers both old and new technologies
★ covers technical and commercial literature
★ covers difficult and hard to trace sources
★ includes over 20 at-a-glance evaluation tables
★ provides an Index of publishers and their addresses

Dr. Crafts-Lighty, Head of Information and Library Services at Celltech Limited, systematically and critically reviews all the important information sources:
• books • conferences • trade periodicals • research periodicals • computer databases • patent • market surveys • directories • organisations • secondary sources

Macmillan Hardcover 400pp **November 1983**
ISBN 0 333 35140 1 **£50.00/$100.00**

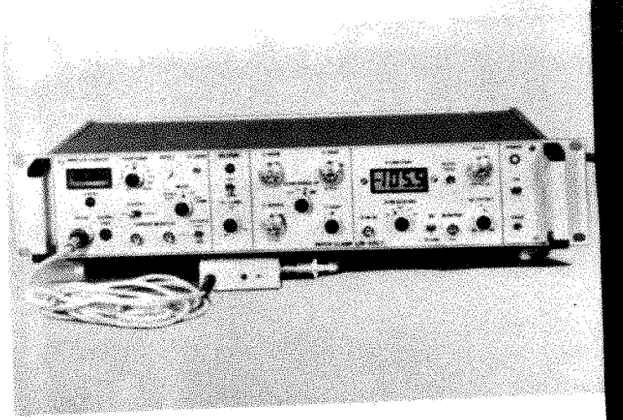
Second Generation
PATCH/WHOLE CELL CLAMP

LIST-MEDICAL
WEST-GERMANY



Unique new technology enables you to measure single channel and whole cell currents using one headstage–one experimental set-up lets you work with patches and cells up to 50 µm.

Instrument noise is so low that it eliminates the electronics as a source of experimental noise.

The EPC-7 is the second generation clamp design by Prof. E. Neher and Dr. F. J. Sigworth of the Max Planck Institute. It is state-of-the-art technology derived from years of pioneering experience with the practical application of patch clamps.

- Internal Resistance Switching 50 GΩ-500 MΩ
- 100 KHz Bandwidth
- Integrated Series-Resistance and Transient-Cancellation Function
- Noise is 0.05 pA RMS at 1 KHz
- Built-in Noise measuring meter
- ...And More

There is nothing else that even comes close ...

The new L/M - EPC - 7 System

INDUSTRIAL IMAGE INSPECTION AT THE RIGHT PRICE

The MV200 system has been designed to provide a simple and inexpensive 'building block' concept for the electronic, electrical, robotic and mechanical industries; to enable a contactless measuring or data acquisition system to be assembled, using a C1700 solid-state camera or other TV camera as input.

☆ **Image enhancement** – for use in low light level applications, image recovery from noisy signals, X-ray processing and enhancement of X-ray or other film photographs.

☆ **Component, recognition menuing and inspection** – when used in conjunction with either solid-state or high stability Vidicon cameras, the systems can be used for component recognition, measurement, grading, counting, area measurement, orientation, positioning etc., and is a useful tool in quality assurance.

☆ **Designed and manufactured in the UK.** With the low cost of the MV200 system and wide range of standard software available, your very own custom-built system becomes economic and viable.

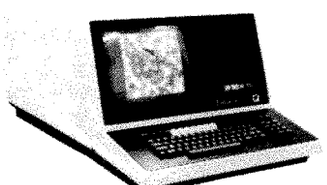
Circle No.02 on Reader Service Card.

They say all Image Analysers are equal, but MAGISCAN is more equal than others.

More applications...
More speed...
More power...
More reliability...
More answers

Magiscan gives you the answers because Magiscan sees, counts, measures and analyses – it interprets what it sees.

If you need to extract data from an image – Magiscan can do it.



All over the world Magiscan is being used to automate time-consuming tasks such as counting asbestos fibres, analysing chromosomes, detecting cracks in vehicle manufacturing, research into timber cells or assessing paper quality – because Magiscan frees the operator to concentrate on the major decisions.

And you don't have to be a computer expert to use it. This compact image analysis system has the most sophisticated "menu" package available. Its clear prompt procedure guides you through each stage of the analysis – or you can leave it to run automatically.

Circle No.11 on Reader Service Card.

No other image analyser offers so much research capability in such a compact unit, so use the speed, power and flexibility of Magiscan – and give yourself more time.

MAGISCAN

Image analysis

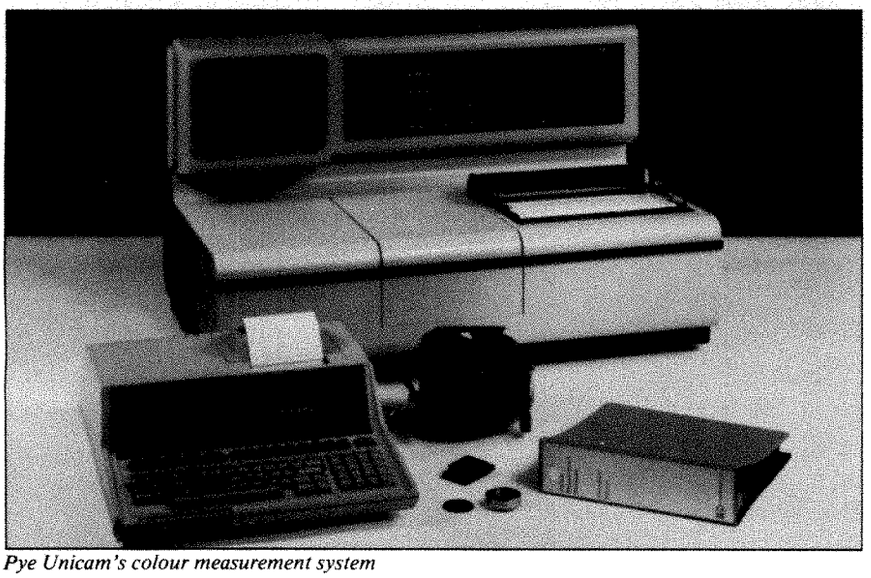
This week's feature focuses on recent developments in image analysis systems

● Spectragraphics has released a new type of computer graphics workstation: the system 1500 Multi-Station. The system 1500 provides a range of interactive graphics features as well as a raster graphics workstation. The system's controller supports from one to four workstations. When configured with a 'communications controller', the system 1500 can support up to 64 workstations. It is offered with a choice of 32-bit parallel interfaces for the IBM, Perkin-Elmer, and Digital Equipment host processors. The system 1500 Multi-Station is designed to accommodate graphics applications such as: computer aided design/computer aided manufacture (CAD/CAM), signal processing, seismic interpretation, command and control, simulation, mapping and molecular modelling. It is available in either monochrome or colour (16, 256, or 4096 simultaneous colours from palettes with up to 16 million colours). The workstation's cathode ray tube is a raster-scan 1024 × 1024 display. Objects can be rotated, scaled and translated. Multiple viewports can be defined and transformed images clipped to their boundaries at real-time rates. In addition, a range of input peripherals is available. This includes keyboards, joysticks, data tablets, digitizers, programmable function switches and programmable function dials.
Circle No. 100 on Reader Service Card.

● A series of image analysis systems is available from Artek. The system 810 is modular and is designed such that all the components are able to interface with peripherals and computers. The second system, the model 982, is Artek's basic image analysis building block. It is designed for use in particle sizing, producing histograms, edge or density counting, area measurement and microscopic applications. Also available is the digitized video system with the 940 memory and image editor. This consists of the video from the model 982 which is digitized into a 512 × 512 × 1 format. The computer functions it can perform include selecting and rejecting objects, filling holes and drawing a measuring frame to match a sample.
Circle No. 101 on Reader Service Card.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Service Card bound inside the journal.

● Two new 6-bit and 8-bit video frame memories have been manufactured by Hamamatsu and are available in the UK through Hakuto International. The units, designated the models C1900 and C1900-01, will digitize and store analog video signals from a television camera and will provide video outputs of the stored image in real time. The C1900 has a 6-bit memory (64 levels) for storing the intensity level of each picture element. It is intended for use with general television cameras as well as Hamamatsu's own range, the C1000 series. The C1900-01 has an 8-bit memory (256 levels) and its own synchronous generator. The camera head of the C1000 or C1145 series non-interlaced television cameras with 512 scanning lines can be connected to the C1900-01 directly, thus eliminating the need for a camera control unit. Image preprocessing functions such as integration, subtraction and image enhancement are not available. These processes may be programmed and commanded by a separate computer.
Circle No. 102 on Reader Service Card.



● Two image analysis systems are available from Artek that can be used in conjunction with the light microscope. The Artek 880 and 980 image analysers allow a choice of scanning field shape, size and position. The systems can analyse three operations — numerical count, object area and aperture area — and these can be reselected using a mode selector. Both the 880 and 980 have bottom light and darkfield illumination capacities. The bottom light can be used when light is able to penetrate the objects being analysed and the darkfield can be used when the contrast between the object and the background is poor. In addition, the 880 has a top light.
Circle No. 103 on Reader Service Card.

● The Photonic microscope system from Hamamatsu allows organisms such as motile cells to be viewed with an optical microscope, something that had hitherto been difficult. The system can be used with optical microscopes with differential interface contrast facilities. A television camera is fitted to a conventional optical microscope equipped for differential interference contrast (DIC) and controlled by an image processor incorporating video frame memories. A range of image processing functions can be performed including background subtraction, integration, contrast and edge enhancements.
Circle No. 104 on Reader Service Card.

● The Zeiss Videoplan 2 is an interactive image analysis system which can perform quantitative analysis of geometric characteristics and data evaluation in the life and material sciences. The system evaluates photographic materials, including X rays, and is equally effective in analysing direct images from video images or light and electron microscopes. Videoplan 2 consists of a digitizer tablet, a microcomputer, a video monitor and a portable keyboard. Dual, double-sided, high-density disk drives and a 64-K user memory plus a 16-K video memory are included. As a stand-alone system, Videoplan 2 can be programmed for turn-key use or it can function as a data generator that interfaces with other computers. The updated Videoplan 2 software includes an array of data acquisition programs, statistics, stereology, data editing and graphic routines for distribution and correlation analyses. Specialized programs are available as options. The computer uses a CP/M operating system and can be programmed in several languages.
Circle No. 105 on Reader Service Card.

The Videoplan 2 interactive image analysis system from Zeiss

Pye Unicam's colour measurement system

● A new colour measurement system is available from Pye Unicam. It is based on the PU 8800 spectrophotometer which uses a software package for the HP 85 computer. The PU 8800 range of instruments incorporates a video display, a built-in recorder and printer options and a choice of side or end-window photomultipliers. The colour measurement software is configured for operation with an HP 85 and coupled through the PU 8800's bi-directional RS 232C interface. Available on tape and disk, the software provides measurement of colour or colour difference in up to three modes — diffuse or total reflectance and transmission. Illuminants A, C, D_{65} and D_{75} are offered, all weighted at 2° and 10° observer angles. Reflectance data on up to 99 standards or samples can be stored on file for immediate recall and the system allows editing of stored black and white calibration values if required. The results can be produced in both tabular and graphical form, along with a listing of the system and calculation conditions, operator identity and date. The instrument can store up to ten user programs.
Circle No. 106 on Reader Service Card.

● Micromeritics has produced an interface for linking a computer to its SediGraph system. The interface, called SediComp, is designed to allow any SediGraph 5000ET to be adapted to Apple II + and Apple IIe microcomputers. SediComp expands the SediGraph data output capability so that it can provide tabular and graphic data in printed or video display format. Programs and data are stored on standard 5¼-inch floppy disks. The SediGraph automates the classical sedimentation technique. The unit can analyse particle sizes in the range from 0.1 μm to 100 μm in a single analysis. The SediComp package includes Apple personal computer boards, master program disks, connecting cables and a user manual.
Circle No. 107 on Reader Service Card.

● Zenith Data Systems has launched two monochrome video monitors known as the ZVM-122 and ZVM-123 green phosphor display, depending upon visual preference. The new monitors are compatible with most business microcomputers and video games, such as the Apple II and III, the IBM personal computer, the Commodore 64 and Vic 20, Texas Instruments' 99/4 and the Atari 800 and 1200, as well as Zenith's own Z100 desktop computer. Designed with a bandwidth of 15 MHz that gives the ability to display more than 800 lines horizontally, the ZVM-122/123 monitors have a rise time of 30 ns. The instrument's 12-inch diagonal screen offers a display with up to 25 lines containing 80 characters each. Each monitor is also equipped with a 40 to 80 character switch. This enables the character size to be increased to accommodate a video format when the computer has a 40-column display.
Circle No. 108 on Reader Service Card.

● The Hamamatsu C1901 and C1901-01 are 16-bit video frame memories with real-time image preprocessing functions. The C1901 is intended for use with raster-scan television cameras, including Hamamatsu's C1000 series and the C1145 range of non-interlaced TV cameras with 512 scanning lines. Since the C1901 contains its own synchronous generator, it is directly compatible with the camera head of the C1000 or C1145. A camera control unit is not required. In contrast, the C1901-01 is designed for use with Hamamatsu's C1181-01 random access camera (image dissector camera) operating in the photon counting mode. It can also be modified for slow scan inputs for the scanning electron microscope. Both models have real-time image preprocessing functions such as integration subtraction, shading correction and image enhancement controlled by using keyboard strokes. In addition, programmable red, green and blue (RGB) outputs are provided.
Circle No. 109 on Reader Service Card.

● Micro Consultants has introduced IDAS, a new generation of digital fluorography equipment. IDAS is a digital fluorography system that interfaces directly to any modern X-ray equipment. The fluoroscopic television output is connected to IDAS via a single coaxial cable. The system is mobile, being trolley mounted. It uses the graphics technology of Micro Consultants' sister company Quantel, and can be expanded with modular software packages. IDAS digital image storage capability can be expanded by interfacing to Centinel, MicroConsultants' medical central image library system. Centinel provides a digital centralized storage and filing system for both pictures and patient records. Images can be stored on Winchester disks and on removable cartridge disks. It can support a number of remote image terminals which have fast access to 500,000 (base system) digitally-stored images.
Circle No. 110 on Reader Service Card.

IDAS from Micro Consultants

● Dapple System's Imageplus + is a software-based image analysis system that can be used in conjunction with a standard Apple IIe computer with 64 K of RAM. The system is boosted with hardware and software options that provide a 256 K memory so that the computer operates at over three times the speed of a standard Apple IIe! This increased capability enables all 64 grey levels to be acquired and stored simultaneously. The system first acquires the image through a video camera, then provides measurements such as area, length, breadth, perimeter and orientation of each feature. Facilities are provided for both manual and automatic modification of the raw image data. Imageplus + can also provide a range of statistical and graphical operations. These include correlation between variables, means, variances and multiple regression. Imageplus + is available in Europe from Miller Systems.
Circle No. 111 on Reader Service Card.

NEW EDITION!

How Britain runs its science...

This highly successful wallchart has now been revised and updated to take account of changes in structure and personnel since the previous edition was published in 1981. It includes the ministerial and other changes which followed the British General Election on 9 June, 1983.

The guide provides a comprehensive survey of the administration of British science, showing the interlocking relationship between science, engineering and medical establishments. It gives a full account of the funding of science in Britain, with details of money spent by government, research councils, industry and universities.

Designed as a fold-out sheet, the 75 × 95cm chart can be carried easily to meetings or hung as a wall poster for permanent reference. The new edition is available at £3.50 or US$7.95 from Nature's offices in Basingstoke or New York.

In the UK and elsewhere: Nature, Brunel Road, Houndmills, Basingstoke, Hants, RG21 2XS, England.

In the US and Canada: Nature, Suite 1503, 15 East 26th Street, New York, NY 10010, USA.

Cheques should be made payable to Nature.

Scientist-Biotechnology

The Unilever Research Laboratory at Vlaardingen is one of the Concern's three large laboratories. Its 1000 employees are engaged in research into food and detergent products and process development.

They carry out industrial research on a multidisciplinary basis. Close contacts are maintained with operating Companies, sister laboratories abroad and Universities.

The job

Our involvement in biotechnology is growing fast. Therefore we would like to contact candidates for a post as

Biotechnologist

in the Process Engineering research group.

Within this group, the section engaged in bioprocessing consists of a staff of 25, including some experienced biotechnologists.

We expect the successful candidate to:

- be knowledgeable in the areas of fermentation and downstream processing, with a good track record as demonstrated by publications, etc.
- be able to identify new opportunities in these areas
- have at least five to ten years industrial research experience
- have managerial experience
- have excellent skills in communication, in order to stimulate further growth of biotechnology within Unilever

If you can meet these requirements please contact Ir R. Keuning, a Director of the Unilever Research Laboratory, who will be able to give further information. Telephone no. 3110 353000 (extension no. 2015).
Written applications in English should be addressed to one of the addresses below:

Citizens of EEC-countries:
Unilever Research Laboratory, Personnel & Organization Department.
Attn. Mrs M. Veenendaal, P.O. Box 114, 3130 AC Vlaardingen, The Netherlands.

US residents:
Lever Research Inc., Attn. Ms Bette Droge, Placement Manager, 45 River Road, Edgewater N.J. 07020, USA.

Unilever.

UMM AL — QURA UNIVERSITY
FACULTY OF APPLIED SCIENCES & ENGINEERING
DEPARTMENT OF MEDICAL SCIENCES

Assistant or Associate Professor in:-

1. **Haematology**
2. **Physiology**
3. **Medical Parisitology**
4. **Pathology**

Qualification: PhD. (Preferably Med-Quat) M.D.

Applications are invited for the above positions tenable immediately for 4 years with the possibility of renewal. Salary depends on qualification and experience.

Applicants are expected to teach and train undergraduate students as well as initiate independent research and participate in working research groups.

Please send CV, and arrange for 2 letters from 2 referees to be sent to:

Dr A. Sultan (Head of Department)
UMM AL-QURA UNIVERSITY
Faculty of Applied Sciences and Engineering,
Department of Medical Sciences,
PO Box 3711, Makkah — Saudi Arabia.

(W693)A

DEPARTMENT HEAD

DEPARTMENT OF BIOLOGICAL SCIENCES DREXEL UNIVERSITY

Applications and nominations are invited for the position of Head of the Department of Biological Sciences beginning September 1, 1984. Drexel University, which emphasizes programs in science and technology and has been a leader in cooperative education for more than sixty years, has approximately 12,000 students in seven colleges. It is situated in the center of Philadelphia not far from a variety of medical schools and other universities. The Biological Sciences Department, one of four departments offering BS, MS, and PhD degrees in the College of Science, is to be expanded considerably in the direction of molecular biology, biochemistry, cell biology, immunology, and other aspects of modern biology. The new Department Head will have the responsibility for recruiting a senior faculty member to fill an endowed Chair and to recruit a number of other persons to fill tenure track positions within the next few years.

The successful candidate is expected to (a) have an earned doctorate in the biological sciences or in a related field; (b) be qualified for tenure as a full professor; (c) have had significant scientific accomplishments; (d) be actively engaged in funded research; (e) have knowledge of funding sources generally in the biological sciences; (f) be experienced in directing graduate research in a PhD granting department; and (g) show evidence of leadership and of a commitment to strong graduate and undergraduate program in modern biological science.

Applications and correspondence should be addressed to Dr. W. William R. Nes, Chairperson, Department Head Search Committee, Department of Biological Sciences, Drexel University, Philadelphia, Pennsylvania, 19104. Applicants should include the names and addresses of three to five persons from whom they will request letters of recommendation. Drexel University is an Affirmative Aciton/Equal Opportunity Employer.

Leukaemia Research Fund Centre at the Institute of Cancer Research

(Director: Dr. M. F. Greaves)

A Leukaemia Research Fund Centre is being established at the Chester Beatty Laboratory of the Institute of Cancer Research in the Fulham Road, London. The Centre will carry out research into the Cellular and Molecular Biology of Human Leukaemia. The following technical and post-doctoral posts will be available from 1st April, 1984.

1. Research Assistant

at the technician or research officer level to help organise molecular biology laboratory and actively participate in its research programme. Experience in recombinant DNA techniques essential. **Ref. 301/B/43.**

2. Research Assistant

at the technician or research officer level to be responsible for monoclonal antibody production. Experience in hybridoma techniques essential. **Ref. 301/B/44.**

3. Research Assistant

at the technician or research officer level to operate Fluorescence Activated Cell Sorter and participate in research programme on haemopoietic progenitor cells. **Ref. 301/B/45.**

Candidates for the above posts should have a degree, HNC or equivalent qualification in appropriate subject. Salary depending on qualifications and experience will be in the range of £5,491 — £7,098 p.a. plus London Allowance of £997 p.a.

4. Research Fellowship

A three year post-doctoral research fellowship is available for studies on the biochemistry of membrane associated proteins of normal and malignant haemopoietic cells. Experience in immunochemistry and membrane protein analysis will be required. Salary in range £7,630 — £8,975 p.a. plus London Allowance of £1,186 p.a. **Ref. 300/G/39.**

Applications for any of the above posts should be sent with a full CV in duplicate to **the Personnel Officer, Institute of Cancer Research, 34 Sumner Place, London, SW7 3NU,** quoting the appropriate reference number.

(1078)A

Faculty Positions in Media Technology

The Massachusetts Institute of Technology has created a new interdisciplinary laboratory to address the invention and creative use of new media. As part of this Media Laboratory's teaching responsibilities, six faculty positions are open in the Department of Architecture. Candidates qualified for any one or more of these openings are invited to submit resumes and any information by February 15, 1984:
Professor Nicholas Negroponte
Director, Media Laboratory
Room NE43-205
Massachusetts Institute of Technology
545 Technology Square
Cambridge, Massachusetts 02139

The positions are in the discipline areas of:

1. film and video engineering
2. computer/graphics
3. personal computation
4. photo-electronics
5. epistemology and learning
6. acoustics and audio engineering

Duties include 50% research and 50% teaching. In each case teaching will include three commitments:

1. an introductory subject in the field
2. a graduate seminar in the faculty person's particular field
3. thesis supervision

Faculty are expected to build research programs from the following existing platforms of sponsored research: human interaction with computers, broadcast technology, learning, signal processing, computer music, electro-optics, graphics and image making.

Applicants must possess a PhD or equivalent, and must have demonstrated ability and interest in research. Teaching experience at the University level is desirable. The positions respectively require professional experience in:

1. television engineering, digital video, telecommunication
2. computer animation, image processing, artificial intelligence
3. human/machine interface, experimental psychology
4. electronic imaging, display technology, 3-D
5. developmental psychology, social science, computation
6. digital audio, real-time signal processing, spatial sound, speech processing, performance technology

Each position can be at either the Assistant or Associate Professor level; salary competitive and to be negotiated. The opening is specifically for the academic year starting March 15, 1984. An earlier starting date is possible.

MIT IS AN EQUAL OPPORTUNITY/ AFFIRMATIVE ACTION EMPLOYER.

(NW240)A

DIRECTOR BIOTECHNOLOGY CENTER

The Ohio State University

The Ohio State University invites applications and nominations for the position of Director of the University's interdisciplinary Biotechnology Center. The candidate should have an earned doctorate and an outstanding record of achievement in an area of Biotechnology such as with microorganisms (including viruses), plants, animals, enzymes, nucleic acid and protein biochemistry, or biochemical engineering, as evidenced by publications, receipt of research grants and activities in national and international scientific organizations. The candidate should also have a demonstrated ability and willingness to interact with other scientists in a University setting.

The Director will provide leadership for and will coordinate the development of interdisciplinary programs in Biotechnology, conduct an active research program in a particular area of interest, and will draw on resources of existing programs in the Colleges of Agriculture, Biological Sciences, Mathematical and Physical Sciences (Chemistry) Engineering, Medicine, Veterinary Medicine and Pharmacy. The Director will have resources to appoint several additional faculty members for the Center beyond those appointments in Biotechnology being made by individual departments.

The Director will provide active leadership in promotion, direction and support of research and instruction activities of the Center, enhance academic excellence, maintain a high level of morale among its faculty, and encourage a spirit of learning among its students.

The Director is responsible for the development and advancement of the research, instruction and service activities of the Biotechnology program, for administering, where appropriate in coordination with other Directors or Deans, the personnel affairs, staffing patterns, budgetary projections and allocations of the Center. The Director reports to the Provost who is the chief academic officer of the University.

The position is available July 1, 1984, or at an earlier date. Salary is highly competitive and commensurate with background and experience.

Applications and nominations should be addressed to Dr. Patrick R. Dugan, Chairman, Search Committee for a Director of Biotechnology Center, The Ohio State University, 203 Bricker Hall, 190 North Oval Mall, Columbus, Ohio 43210. Deadline for applications and nominations is March 1, 1984.

The Ohio State University is an Affirmative Action/Equal Employment Opportunity Employer. (NW233)A

Am Institut für Med. Mikrobiologie der Johannes Gutenberg-Universität (Fachbereich 04 Medizin) ist eine

C3 Professur (Beamtenstelle auf Lebenszeit) für das Fachgebiet

MOLEKULARGENETIK

erstmals zu besetzen. Bewerber (Mediziner oder Naturwissenschaftler) sollen auf dem Gebiet der Prokaryonten und/oder Eukaryonten international ausgewiesen sein. Darüberhinaus wird Bereitschaft zur Kooperation mit den Forschungsgruppen des Institutes auf den Gebieten "Immunologie" und "Mikrobielle Pathogenitätsfaktoren" vorausgesetzt. Laborarraum von 250 qm und apparative sowie personelle Grundausstattung sind vorhanden.

Bewerbungen mit den üblichen Unterlagen sind bis vier Wochen nach Erscheinen dieser Anzeige zu richten an den Dekan des Fachbereichs Medizin der Johannes Gutenberg-Universität Mainz, Am Pulverturm 13, 6500 Mainz, Tel: 06131/17-3180. (W682)A

des Chercheurs qui trouvent !

Ils existent, nous travaillons avec eux...
Si la découverte de MEDICAMENTS vous tente,
rejoignez notre Centre de Recherche situé à Paris.

Nous créons encore des départements en

pharmacologie

Nous recherchons leurs

Directeurs

L'un sera spécialisé en Rhumatologie, il aura des connaissances approfondies • en immunologie, • sur les phénomènes biochimiques associés à l'inflammation, • en analgésie.

L'autre sera spécialisé en Neuro-Psychopharmacologie privilégiant l'abord biochimique.

Pour un département existant, nous recrutons un

Cadre de recherches

en Pneumologie (niveau 3e cycle en Sciences ou équivalent).

Il aura des connaissances en physiologie ou pharmacologie respiratoire, circulation pulmonaire, exploration fonctionnelle et pathologie expérimentale.

Dernière précision, notre Entreprise est française, du secteur privé. Elle s'enorgueillit d'être active au niveau mondial puisqu'elle exporte la moitié de ses découvertes.

Merci d'adresser lettre manuscrite rédigée en français, C.V. + photo, sous réf. 5500 à Média-System, 104 rue Réaumur 75002 Paris qui transmettra.

(W699)A

UNIVERSITY OF BERGEN, NORWAY

UNIVERSITY LECTURERSHIP IN SEDIMENTOLOGY

A position as *university lecturer* is vacant at the Geological Institute (Dept. A), University of Bergen, Norway. Applicants must have an MSc, PhD or equivalent qualifications and competence in sedimentology (preferably clastic sedimentology). Experience in sedimentary mineralogy and geochemistry will be advantageous.

The vacant position is in association with the research group in sedimentology/petroleum geology which is composed, in addition to the advertised position, of a scientific staff of 5. The successful candidate must be able to take part in teaching at both undergraduate and postgraduate levels according to the requirements of the institute and follow the regulations which apply for the position. Applications from women are encouraged. Further particulars about the lectureship may be obtained from the Secretary of the Faculty of Sciences, PO Box 25, 5014 Bergen Universitet, Norway. The salary will be in the range NKr. 123.496 — NKr. 162.917.

Applications, with a complete curriculum vitae, copies of degrees and testimonials together with one set of scientific publications and a list of these in triplicate should be sent to the University of Bergen, Personnel Department, PO Box 25, 5014 Bergen — Universitet, Norway, by 20th March 1984.

(W677)A

HERIOT-WATT UNIVERSITY
DEPARTMENT OF PHYSICS

RESEARCH ASSOCIATES — SEMICONDUCTOR OPTICAL BISTABILITY

The bistability research team, under the direction of Professor S D Smith FRS, presently numbers fifteen scientists. Research objectives include studies of the nonlinearities that are the physical origin of semiconductor optical bistability, assessment of new materials for bistability in the infrared, near-infrared and visible spectral regions, investigations of bistable characteristics, and the development of novel devices. Achievement of the optically bistable switch has caused speculation of device applications ranging from fibre communication link repeater elements to optical parallel processing and optical signal computing. The group has a number of collaborative projects, both with Industry (through the Joint Optoelectronic Research Scheme) and with Universities throughout Europe (through the European Joint Optical Bistability Project).

Applications are invited from candidates with PhD experience in semiconductors/optical properties, optoelectronic devices, laser physics, or theory of optical properties of semiconductors.

Salaries will be in the range £7,190 to £11,615, according to age and experience.

Informal enquiries may be made to Dr B. S. Wherrett, Department of Physics — Tel: 031-449 5111 ext 2223.

Application forms are available from the Staff Officer, Heriot-Watt University, Chambers Street, Edinburgh EH1 1HX (please quote ref. no. 3/84).

(1043)A

Research Scientist- Animal Physiology

Harefield, Middx. c.£14,000

Glaxo Animal Health Limited, part of the well known Glaxo Group, is a young, highly autonomous and rapidly expanding company with UK market leadership in ethical veterinary products, and worldwide responsibility for the Group's animal health interests.

An opportunity now exists for a highly capable research scientist to join the company's physiology team within a department which is responsible for researching and developing innovative products designed to increase animal production.

Candidates should have gained a PhD in genuinely innovative research — preferably in the field of biochemistry, cell biology, metabolic science or nutritional physiology. Particular areas of interest include intermediary metabolism, muscle nutrition and development, digestion and absorption, fat or muscle cell culture, in vitro tissue culture, tissue residues studies, and protein and fat metabolism.

In addition to an original, fresh approach to the study of metabolism and growth, candidates should possess the ability to operate effectively with the minimum of supervision in a committed, small-team environment, together with communication/presentation skills of the highest order.

A starting salary of around the level indicated is envisaged, though this need not prove a limiting factor for high-calibre candidates. Generous benefits include guaranteed bonus, site allowance, free pension scheme, and, if appropriate, assistance with relocation; excellent sports and social facilities are also available.

For an application form, please contact Mrs Moira Model, Company Personnel Officer, Glaxo Animal Health Limited, Breakspear Road South, Harefield, Uxbridge, Middlesex UB9 6LS. Telephone: Ruislip (089 56) 30266.

Glaxo Animal Health Limited (1050)A

National Hellenic Research Foundation

Two research assistants, PhD, Molecular Biology, to take part in programs on Structure and function of nuclear RNP/carcinogens and hormonally regulated genes.

Send full curriculum to: Mrs. Th. Stefanou, Institute of Biological Research, National Hellenic Research Foundation, Vassileos Constantinou 48, Athens, Greece. (W680)A

MEMORIAL UNIVERSITY OF NEWFOUNDLAND
Sir Wilfred Grenfell College
The Department of Physics invites applications for a tenure-track position at the rank of

ASSISTANT OR ASSOCIATE PROFESSOR

at the Sir Wilfred Grenfell College campus of the University, located in Corner Brook, Newfoundland, subject to final budgetary approval. The College offers a full range of courses at the first and second-year levels. The primary responsibilities of the position will be instruction in the first and second-year Physics courses. The campus accommodates about 700 students in a residential setting and is located in a community of about 30,000 population.

Applications, including curriculum vitae and the names of three referees, should be sent to: Dr. D. H. Rendell, Head, Department of Physics, Memorial University of Newfoundland, St. John's, Nfld. A1B 3X7. (NW239)A

(United Medical & Dental Schools)

POSTDOCTORAL POSITION IN HUMAN NEUROPHYSIOLOGY

Applications are invited for a post-doctoral position at the Sherrington School of Physiology to study the organization of central synaptic input to motoneurones in man. The position is supported by the MRC and will be available from January 1984. Knowledge of spike train analysis would be an advantage but is not essential.

For more details please contact Dr John Stephens, Sherrington School of Physiology, St Thomas's Hospital Medical School, London SE1 7EH. (1002)A

Director

MRC Biostatistics Unit

The Medical Research Council invites applications for the post of full-time Director of the Biostatistics Unit to succeed Dr I Sutherland.

The person appointed will have an established reputation as a scientific investigator in biomedical statistics, be able to develop the Unit's research programme, and have the ability to lead, manage and co-ordinate the activities of a research team. It is not essential that he or she possess a medical qualification.

The Unit is concerned with the development and advancement of statistical methodology, both fundamental and as applied to medical problems, and with research into the epidemiology of disease. An important function at present is the provision of statistical advice to Council Units, Council Committees, and other scientific workers. The precise scope and emphasis of the Unit's future programme will be a matter for discussion between the successful candidate and the Council, but it is expected that the programme will include fundamental studies, both purely theoretical and problem-related. A candidate who wished the Unit to specialise in a particular line of biomedical research in which statistical methods play a prominent part should put their proposals forward.

The Unit is at present accommodated in the MRC Centre at the University Medical School, Cambridge; however, new accommodation may need to be sought on the appointment of a new Director. The present staff complement is 15, including 5 scientific staff.

An appointment to the Council's staff will be in accordance with the Council's terms and conditions of service, and with superannuation under the MRC Pension Scheme. The salary will be within the Council's Special Appointments Grade, which is equivalent to the Universities' professorial range. If required, assistance may be given with house sale/purchase expenses. The present Director is not due to retire until September 1986, but it is hoped that his successor will be able to join the Unit as Director-designate before that date.

Applications in the form of a short statement (not exceeding 1,000 words) outlining in general terms the scientific programme which the applicant would propose for the Unit, together with a *curriculum vitae*, list of publications, and the names of three referees, should be submitted not later than 16 March 1984 to the Secretary of the Council at the address below.

Additional information, including details of the current programme of the Unit, may be obtained from Mr K Hammond, MRC Headquarters Office, 20 Park Crescent, London W1N 4AL; telephone 01-636 5422 ext. 336.

AGRICULTURAL BIOTECHNOLOGY

Shell Development Company is seeking scientists with significant records of achievement who are interested in applying their skills to agronomic research.

Positions are available for outstanding Ph.D.-level scientists with training in one of the following:

- Agricultural Microbiology
- Plant Molecular Biology
- Plant/Invertebrate Pathology
- Plant Cell and Tissue Culture

Shell Development Company at Modesto, California offers an outstanding research environment, a reasonable cost of living, and attractive salaries and benefits. Modesto is close to the San Francisco Bay Area and the Sierra Nevada Mountains. Shell's current staff includes a strong team of innovative scientists with a record of technical accomplishment and commercial success in agrochemicals research.

Applicants should be U. S. Citizens or have permanent resident visa. Interested applicants should send a résumé, in confidence, to: Manager, Employee Relations, Shell Development Company, Biological Sciences Research Center, P.O. Box 4248, Modesto, CA 95352.

Analytical Chemist
Saudi Arabia
c. £18,250 p.a. tax-free

IAL have been providing high technological expertise to countries throughout the world for over 35 years. We are presently engaged in an environmental protection programme in Saudi Arabia and can offer a new opportunity to an experienced Analytical Chemist.

Based in Jeddah, you will be visiting locations all over the country to monitor the operations of fixed air quality stations. From mobile laboratories, equipped to the highest standards, you will be collecting and analysing field samples for standard air and water parameters. You will also be transferring your expertise to Saudi staff, giving support and assistance to on-the-job training programmes.

You should have a degree in Chemistry, ideally with experience in Analytical Chemistry and some basic knowledge of Biology. You should also have at least five years experience in either a modern analytical laboratory or in the laboratory services of a statutory body dealing with the monitoring of air or water quality.

As well as an attractive tax-free salary, paid in Saudi Riyals (at the currrent exchange rate of SR5.0=£1), you will enjoy excellent benefits such as rent free accommodation, life insurance and generous leave entirlement.

Please apply to the Senior Recruitment Officer, IAL, Aeradio House, Hayes Road, Southall, Middx. UB2 5NJ. Tel: 01-574 5134. Please quote Ref. S006.

British Postgraduate Medical Federation

THE CARDIOTHORACIC INSTITUTE LECTURER (NON-CLINICAL) IN ALLERGY AND CLINICAL IMMUNOLOGY

Applications are invited for a Scientific Assistant (Lecturer grade) under a Medical Research Council programme grant entitled "Allergy and the Eosinophil". Applicants should normally be under the age of 32 and have a PhD (or equivalent) in pharmacology, biochemistry, immunology or cell biology. The post is tenable for up to five years. Applications from scientists in industry, on secondment, are also invited. It is hoped that this post will be taken up as soon after 1st May as possible. Salary will be on the non-clinical lecturer scale currently £7,190 + £1,186 London Allowance, rising to £14,125 + £1,186.

Applications in duplicate in the form of a curriculum vitae giving full details of experience, and the names and addresses of two referees, should be sent to the Secretary, Cardiothoracic Institute, Fulham Road, London SW3 6HP, from whom further details are available. The closing date is 1st March, 1984. (ACM2). (1070)A

UNIVERSITY OF PAPUA NEW GUINEA — PORT MORESBY

PROFESSOR OF HUMAN BIOLOGY

(P821001/84) (Department of Human Biology)
(Re-advertisement)

Applications are invited for the above post.

The Department of Human Biology comprises the pre-clinical disciplines of anatomy, physiology, biochemistry and pharmacology, and is responsible for the teaching of both undergraduate and postgraduate medical and dental students. The Department aims to present the basic medical sciences in an integrated fashion, with emphasis on clinical relevance. Clinical contact is introduced from the outset of the undergraduate course. An active programme of population-based and laboratory research is underway in the Department.

The successful applicant will have a distinguished academic record with one of the pre-clinical sciences as their main field of interest, but applications from clinicians with an especial interest in pre-clinical medical education will be particularly welcomed. A medical qualification would be a distinct advantage, although a person who is not medically qualified may apply. Teaching and/or research experience in a developing country would also be an advantage.

The appointee will provide academic leadership, participate in teaching in the basic medical sciences, and stimulate research. He will also promote the development of Papua New Guinean national academic staff. Opportunities will exist for maintaining links with clinical medicine by suitably qualified practitioners, and this would be welcomed in the interest of maintaining close correlation between the pre-clinical teaching programme and clinical practice. The Professor will not necessarily have any administrative responsibilities, although he can be elected to positions carrying such responsibilities.

Salary: K22,820 per annum, plus gratuity.

OTHER CONDITIONS: The successful applicant will be normally offered a contract for a three year appointment ending at the end of a semester. The gratuity entitlement is based on 24% of salary earned and is payable in instalments or a lump sum and is taxed at a flat rate of 2%. In addition to the salaries quoted above, the main benefits include: support for approved research; rent-free accommodation; appointment and repatriation airfares for appointee and dependants; financial assistance towards the cost of transporting personal effects to and from PNG: 6 weeks annual recreation leave with home airfares available after each 18 months of continous service; generous education subsidies for children attending schools in PNG or overseas; a salary continuation scheme to cover extended illness or disability. Applicants who wish to arrange secondment from their home institutions will be welcomed. The terms and conditions are currently under review.

Applications will be treated as strictly confidential and should include a full curriculum vitae, a recent small photograph and the names and addresses of three referees. In order to expedite the appointment procedure, applicants are advised to ask their referees to send confidential reports directly to the University without waiting to be contacted.

Applications quoting position number, should be forwarded to the Assistant Secretary (Staffing), University of Papua New Guinea, PO Box 320, UNIVERSITY, Papua New Guinea, to reach him no later than *31 March 1984*.

Candidates in the UK should also send a copy of their application to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. (W692)A

MRC
Medical Research Council

An initial contract of 2 years will be offered. Salary will be determined by qualifications and experience.

Further details and applications forms may be obtained from Miss K. Douglas. The closing date for applications is 14 February 1984. (W686)A

ST GEORGE'S HOSPITAL MEDICAL SCHOOL
(University of London)
POSTDOCTORAL RESEARCH FELLOW
(Immunology Department)

Required for 2 year CRC funded project to work on the in vitro immune response of lymphocytes from patients with Chronic Lymphocytic Leukaemia. Applicants should have a background in Immunology or Biochemistry with tissue culture experience. Initial salary up to £7,630 pa plus £1,186 pa London allowance.

Further details and application form from the Establishment Officer, St George's Hospital Medical School, Cranmer Terrace SW17 0RE. Closing date 22nd February. (1083)A

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL
(University of London)
DEPARTMENT OF MEDICINE
MEDICAL LABORATORY SCIENTIFIC OFFICER

to assist in a Medical Research Council supported project to investigate the metabolism of vitamin D in health and in clinical disorders of calcium homeostasis. The work will include isolation of the metabolites by high pressure liquid chromatography and their measurement by radioimmunoassay.

Applicants should have a good Honours Degree in Biological Sciences. The appointment is for three years commencing early 1984. Salary is in the range of £7,140 — £7,434 (including London Allowance), according to age and experience.

Applications (including telephone numbers) with details of two referees to: professor J L H O'Riordan, Department of Medicine, The Middlesex Hospital, Mortimer Street, London W1N 8AA.

(1059)A

GRADUATE Research Assistant funded by the Cancer Research Campaign required to work on the pharmacokinetics of cancer chemotherapy in man in the joint departments of Clinical Pharmacology and Medical Oncology with particular reference to analytical and electrochemical methods. The post is available immediately, for two years, with the possibility of a third year. Salary scale: £6,310 — £7,190 plus £1,186 per annum London Allowance, and superannuation. Apply in writing to the Deputy Secretary, United Medical and Dental Schools, Guy's Hospital Medical School, London Bridge, London SE1 9RT, quoting Ref. MO1. (1062)A

POST-DOCTORAL POSITIONS

Two post-doctoral positions are currently available in the area of cardiovascular research.

One position is available for an applicant with a background in pharmacology and smooth muscle research and will involve the functional characterization of alpha adrenoceptors in vascular smooth muscle.

The second position is for someone with a neuroscience/anatomy background and an interest in pursuing projects related to a number of morphological aspects concerning cardiovascular control mechanisms (brainstem and spinal cord structure and function, peripheral autonomic innervation, role of substance P in cardiovascular formation, and structure of the heart and blood vessels).

The annual salary, depending on experience, will commence at $18,000, and partial re-location expenses are available.

Send curriculum vitae, statement of research interests, and the names of three academic references to: Dr C R Triggle, Associate Dean of Basic Medical Sciences, Faculty of Medicine, Memorial University of Newfoundland, St John's, Newfoundland, Canada A1B 3V6.

(NW232)A

THE AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited from suitably qualified persons for appointment to the following position:

FACULTY OF SCIENCE
DEPARTMENT OF PHYSICS
RESEARCH FELLOW

The appointee will be required to participate in and supervise the research with free-piston shock tunnel and shock tube facilities. The research interests include: high enthalpy hypersonic flows, non-equilibrium processes in these flows, shock-propogation, and problems in fundamental atomic physics and astrophysics related to shock heated gases.

The appointee should have a PhD and experience in a field relevant to the above research.

During 1984 the appointee will be required to participate in the teaching within the Department and in fields related to the above research.

The appointment is to 31 December 1986.

Closing Date: 28 February 1984.

Conditions of appointment: Salary will be in accordance with qualifications and experience within the range: Research Fellow $A23,394 — $A30,734. Current exchange rate is $A1 = UK62p.

Grants are provided towards travel and removal. Assistance towards housing is given to an appointee from outside Canberra. Eligible appointees will be required to join the Superannuation Scheme for Australian Universities. The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should write to the Registrar of the University, GPO Box 4, Canberra, ACT 2601, Australia, or to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, for further particulars before submitting applications.

(W696)A

Medical Research Council Laboratories
The Gambia

Immunologist

Applications are invited from post-doctoral immunologists for a post at the MRC Laboratories, Fajara, The Gambia. The successful candidate for this post will join a group studying the immune response to malaria in man and he or she will be encouraged to study some of the soluble factors produced by human mononuclear and adherent cells which control the growth of malaria parasites *in vitro*. Previous experience in biochemistry and immunochemistry is, therefore, required.

Virologist

Applications are invited for a post of virologist at the MRC Laboratories, Fajara, The Gambia. The successful applicant for this post will join a team embarking on a new study of acute respiratory infections in Gambian children and he or she will be responsible for viral isolations and identification. Previous experience of respiratory virus isolation is required.

An initial contract of 2 years will be offered. Salary will be determined by qualifications and experience.

MRC
Medical Research Council

Applications should be submitted to Miss M. Grenham from whom further details may be obtained. Medical Research Council, 20 Park Crescent, London W1N 4AL. The closing date for applications is 29th February, 1984.

(W694)A

THE UNIVERSITY OF LEEDS

DEPARTMENT OF PHYSIOLOGY

LECTURER

Applications are invited fo above post available fro September 1984.

Previous experience of experimental techniques of micropuncture or renal micr fusion in vitro would be an adva both in relation to research an teaching duties of the post.

Salary on the scale for Lect (£7,190 — £14,125) according t qualifications and experience.

Informal enquiries may be ma Professor B R Jewell (tel 431751 ext 7267).

Application forms and fu particulars may be obtained fro Registrar, The University, Leed 9JT quoting reference no 104/ Closing date for applica 20 February 1984. (109

BIRKBECK COLLEGE
(UNIVERSITY OF LONDON)
SERC DARESBURY LABORATORY

JOINT APPOINTMENT OF POSTDOCTORAL RESEARCH FELLOW IN PROTEIN CRYSTALLOGRAPHY

Applications are invited from protein crystallographers who have recently completed their PhD's for a five-year joint appointment. The successful applicant will be responsible for developing the use of synchrotron X-radiation for the study of protein crystals with especial emphasis on high resolution data collection and solution of the phase problem using anomalous dispersion techniques, with particular regard to projects developed at Birkbeck College by the Molecular Biology Laboratory of the Department of Crystallography. The successful applicant will need to be prepared to spend his/her time equally between Birkbeck where he/she will be responsible for preparation of crystals and development of the analyses, and Daresbury where X-ray data will be collected and experimental techniques developed. When at Daresbury, the successful applicant will be a member of the group responsible for providing general support to protein crystallographers using the synchrotron radiation source.

Initial salary, according to age and experience, will be between £8,376 pa and £9,716 pa including London Weighting.

Applications including CV and names of two referees should be sent to the Assistant Secretary (Personnel), Birkbeck College, Malet Street, London, WC1E 7HX, England. (1080)A

UNIVERSITY OF WARWICK

POSTDOCTORAL FELLOWSHIP

Applications are invited for a two year postdoctoral fellowship to study the synthesis and metal ion coordination chemistry of new polyazamacrocyclic ligands. Salary on the Research Range IA scale: £7,190 — £11,615 pa.

For further details contact Dr P Moore, Department of Chemistry and Molecular Sciences, University of Warwick, Coventry CV4 7AL. (1051)E

UNIVERSITY OF ABERDEEN
DEPARTMENT OF BIO-MEDICAL PHYSICS AND BIO-ENGINEERING

LECTURESHIP IN MODERN ELECTRONICS

Internationally recognised Department seeks Lecturer with interests in modern electronic techniques and their applications to teach and practice electronic design, particularly digital, and to join in the activities of a well equipped electronics workshop designing, fabricating and servicing modern electronics in bio-medical research and routine hospital work.

Opportunities for research. Additional experience in eg vacuum, high frequency, microwave and high voltage technology helpful but not essential.

Salary on Lecturer scale (£7,190 — £14,125 per annum) with appropriate placing.

Further particulars and application forms from The Secretary, The University, Aberdeen, with whom applications (2 Copies) should be lodged by 17 February 1984. (1054)A

POST DOCTORAL RESEARCH ASSOCIATE

to conduct experiments in which neurotransmitters and enzymes are measured in experimental animals or human volunteers after being subjected to a variety of nutritional conditions including trace element deficiencies. Requires PhD in Biochemistry with experience in enzymology, neurochemistry and HPLC. Prefer one-two years post doctoral experience. Anticipated beginning date for appointment is May 1, 1984. Salary $15,0 $17,000 plus benefits, one appointment with possibilit renewal.

Send CV, names of references, and relevent publica to: Ms Alice Hoffert, H Nutrition Research Center, PO 7166, University Station, Forks, ND 58202.

Marketing Opportunities in Animal Health

Continued expansion of our animal health business has led to the creation of three challenging new positions for which we now seek applications.

Product Executives

Two people required to assist the Marketing Manager in extending our share in the market for a wide range of veterinary pharmaceuticals and biologicals. Candidates must show the ability to provide a comprehensive marketing resource and to draw up and implement effective marketing plans.

Product Development Executive

To assist the Product Development Manager in preparing data and dossiers for new products for the animal health market. Some years of marketing experience in industry with a qualification in marketing or a relevant university degree are a pre-requisite for all positions.

The company is a multi-national and a leader in this field offering an attractive salary, contributory pension scheme with free life assurance, free membership of P.P.P. and a generous allowance for anyone who has to relocate. The location is Milton Keynes where housing is readily available for purchase or rent.

For an application form write or telephone A. Forrest, Personnel Manager, Hoechst UK Limited, Walton Manor, Walton, Milton Keynes, MK7 7AJ. Telephone 0908 665050.

INSTITUTE OF CHILD HEALTH
University of London

POSTDOCTORAL RESEARCH FELLOW

Applications are invited for a post-doctoral research fellow to join a small, multi-disciplinary highly motivated, group working on early post-natal structural development of the pulmonary vasculature with reference to changes observed during the development of pulmonary vascular disease in children with congenital heart disease. Practical experience in immunohistochemical and immunofluorescent techniques is essential. The position is available for two years. Initial salary £8,376 per annum (inclusive of London Weighting) in accordance with University Scale 1A for Academic Related Research Staff.

Applicants should send curriculum vitae and the names of two referees to Dr Sheila G Haworth, Department of Paediatric Cardiology, The Hospital for Sick Children, Great Ormond Street, London WC1. (1067)A

ST MARY'S HOSPITAL MEDICAL SCHOOL
(University of London)
Norfolk Place,
London W2 1PG
DEPARTMENT OF CLINICAL PHARMACOLOGY

POST-DOCTORAL RESEARCH FELLOW (NON-CLINICAL) IN CARDIOVASCULAR PHARMACOLOGY

The appointment is for one year in the first instance, with a possible extension to a maximum of three years.

The research programme involves the investigation of drug actions on isolated human blood vessels. Applicants with previous experience in adrenergic and/or cardiovascular pharmacology will be preferred.

Salary range: £6,310 — £8,530 + £1,186 London Allowance.

Applications and names of two referees should be sent to the Assistant Secretary (Personnel) at above address no later than 3 February 1984. (998)A

UNIVERSITY OF EDINBURGH
DEPARTMENT OF CLINICAL SURGERY
Applications are invited for the post of
DATA MANAGER/ COORDINATOR

for a research project within the University Department of Clinical Surgery. Applicants need not be medically qualified, but should have a scientific training and knowledge of, or experience in, the medical field.

Salary will be at an appropriate point on the scale £7,190 — £10,250. A full-time appointment would be preferred, but part-time would be considered. The appointment will be for one year in the first instance.

Further particulars are available from Professor A P M Forrest, University Department of Clinical Surgery, The Royal Infirmary, Edinburgh EH3 9YW, with whom applications, (2 copies) including curriculum vitae and the names of two referees, should be lodged not later than 17th February, 1984.

Please quote reference no 7042. (1063)A

STATE OF KUWAIT
UNIVERSITY OF KUWAIT
FACULTY OF MEDICINE — HEALTH SCIENCE CENTRE

Advertisement

CHIEF TECHNICIAN IN THE DEPARTMENT OF PHARMACOLOGY

Applications are invited for the post of Chief Technician in the Department of Pharmacology. Candidates should have experience in modern analytical techniques, especially Gas-Chromatography and Mass-Spectrometry and hold the F.I.M.L.S., or equivalent qualification, with fifteen years' experience including training.

Salary will be in the range KD 450-512 per month, (KD 1 = £1.8, US$ 3.5, approx.). There is no income tax in Kuwait and currency is transferable without restriction. Free, furnished, air-conditioned accommodation is provided and electricity and water supplied free of charge. Sixty days paid annual leave for each completed year of employment, and annual economy class return air tickets to the country of citizenship or permanent residence are provided for the appointee, spouse and three dependent children. Free medical treatment is available under the State Health Service.

Applications should be submitted to: The Dean, Faculty of Medicine, University of Kuwait Health Science Centre, PO Box 24923 Safat, Kuwait, with detailed curriculum vitae in duplicate, recent passport photograph, and the names of three referees, to arrive no later than 15th February 1984.

SEMINARS and SYMPOSIA

St George's Hospital Medical School Cell Surface Research Fund

The second annual Symposium will be held on Friday 13 April 1984 at St George's HMS, London SW17 on

THE ELECTRICAL PROPERTIES OF THE CELL SURFACE AND NEUROLOGICAL DISEASE

Chairmen: Lord Adrian FRS (Cambridge) & J. Newsom-Davis (Royal Free HMS, London)

Speakers: S. Bevan (UC, London), J. O. Dolly (Imp. Coll, London), A. de Hemptinne (Ghent), D. A. Heyden FRS (Cambridge), J. S. Kelly (St George's HMS, London), R. McBurney (Newcastle), C. A. Pasternak (St George's HMS, London) and T. A. Sears (Inst. Neurol., London)

Intending participants are invited to present posters at the meeting: brief abstracts should be sent before 1 March to Mrs V. Marvell, Department of Biochemistry, St George's HMS, London SW17 0RE; Tel: 01-672 1255, ext 4733, from whom further information can be obtained.

The Symposium forms part of the UNESCO Cooperative Research Programme in Biomaterials and Biotechnology in the European and North American Region.

The Symposium will be preceded by a Cell Surface Research Fund — UNESCO advanced training course on

MODERN METHODS FOR MEASURING MEMBRANE AND SURFACE POTENTIALS

from Monday 9 April — Thursday 12 April 1984 at St George's HMS

Instructors: C. L. Bashford, T. B. Bolton, J. M. Graham & J. S. Kelly

Course fee, inclusive of full board and lodging from Sunday 8 April — Friday 13 April (incl. attendance at the Symposium), £250

Financial assistance towards travel and other costs for applicants from outside UK is available.

Application forms and other information before 1 March from Dr C. L. Bashford, Department of Biochemistry, St George's HMS, London SW17 0RE, Tel: 01-672 1255 ext 5012

Friedrich Miescher-Institut, Basel, Switzerland
POSTDOCTORAL FELLOWSHIP IN MOLECULAR NEUROBIOLOGY

Applications are invited for an internally funded fellowship, of three years maximum duration, to work on the expression of neuron-specific proteins in developing brain using recombinant DNA techniques. A good training and demonstrated ability in molecular biology are required. The Institute provides outstanding facilities in a purely research environment. **Inquiries should be addressed to Dr. A. Matus, Friedrich Miescher-Institut, PO Box 2543, CH-4002, Basel, Switzerland.** (W700)E

E M B O

European Molecular Biology Organization

LONG TERM FELLOWSHIPS IN MOLECULAR BIOLOGY SPRING 1984 AWARDS

Next deadline: February 16, 1984

EMBO long term post-doctoral fellowships are awarded to promote the development of molecular biology and allied research in Europe and Israel. To be eligible a candidate must hold a doctorate degree and the exchange must involve a laboratory in Western Europe or Israel. EMBO fellowships are not, however, awarded for exchanges between laboratories within one country. Long term fellowships are awarded initially for one year, but depending on a review of progress, they may be renewed for a second year. In cases of exceptional scientific merit renewal for a third year is possible. The fellowship comprises a return travel allowance for the fellow and any dependents and a stipend and dependents' allowance.

Since the selection procedure may include an interview, candidates are requested to respect the deadline for complete applications which is February 16, 1984. Successful candidates will be notified of their awards immediately after the meeting of the selection committee, which is on April 27, 1984.

Application forms and further details may be obtained from Dr J. Tooze, Executive Secretary, European Molecular Biology Organization, Postfach 1022.40, 69 Heidelberg 1, F.R. Germany. (W531)E

EMBL

European Molecular Biology Laboratory

PREDOCTORAL FELLOWSHIPS

The European Molecular Biology Laboratory is to award a limited number (6-8) of predoctoral fellowships for graduates wishing to study for a PhD at EMBL Heidelberg or its outstations at DESY, Hamburg or ILL, Grenoble. The areas of research in Heidelberg include membrane biology, cellular differentiation, analysis of the structure of membrane proteins and protein nucleic acid complexes and the structure and regulation of genes in procaryotes and eucaryotes. At the EMBL outstations the research centres on the elucidation of biological structures using either synchrotron radiation (Hamburg) or neutron beams (Grenoble).

To be eligible, candidates must hold, or anticipate receiving in 1984, a first or upper second class honours degree, a masters degree or a diplom in biological sciences, physical sciences or mathematics. Preference will be given to candidates from the member states of EMBL and EMBC namely: Austria, Belgium, Denmark, Finland, France, Federal Republic of Germany, Greece, Iceland, Ireland, Israel, Italy, Netherlands, Norway, Spain, Sweden, Switzerland, United Kingdom.

Short listed candidates will be asked to visit EMBL (travel expenses reimbursed) for an interview. Those awarded predoctoral fellowships will be expected to begin working at EMBL in September 1984. The normal duration of the fellowships will be 3 years subject to annual review.

The closing date for completed applications is February 1st 1984. Successful candidates will be notified by the end of April 1984.

Application forms and a catalogue giving further information about the research at EMBL and the groups participating in the Laboratory's predoctoral programme is available on request from Dr J. Tooze, Predoctoral Programme, EMBL, Postfach 10.2209, 6900 Heidelberg, F.R. Germany. (W511)E

DEPARTMENT OF EDUCATION, DUBLIN

POST-DOCTORAL RESEARCH FELLOWSHIPS 1984/85

Applications are invited for research fellowships in science (excludin medical and social science), engineering and architecture tenable in an one of the following institutions in Ireland:-

University College, Dublin.
University College, Cork.
University College, Galway.
Trinity College, Dublin.
St. Patrick's College, Maynooth.
The National Institute for Higher Education, Dublin.
The National Institute for Higher Education, Limerick.
An Foras Talúntais
(The Agricultural Institute), Dublin 4.
The Institute for Industrial Research and Standards, Dublin 9.
An Foras Forbartha, Dublin 4.
The Colleges of Technology, Kevin St. and Bolton St., Dublin.

Fellowships will be tenable for a period of two years with the possibilit of an extension for a third year.

Applicants should hold the degree of PhD or have equivalent researc experience. Applications will be considered from engineers, architect or technologists with suitable industrial experience. Candidates mus be under the age of 30 years and preferably under the age of 28 years or 31 March, 1984.

Appointments will be effective from a date not earlier than 1st October 1984. The initial salary, which will depend upon qualifications an experience, will normally be within the range IR£6,961 to IR£7,876 pe annum, but awards of up to IR£9,097 may be made in the case o engineers, architects and technologists whose industrial experience o other special circumstances warrant it.

Full particulars of the scheme including application forms ma be obtained from the Secretary, Department of Education (Headquarters Section 3), Marlboro' Street, Dublin 1, to whom applications for fellowships should be forwarded. The latest date for the receipt of applications is 31st March, 1984. (1091)E

LSB LEAKEY FOUNDATION RESEARCH FELLOWSHIP FIELD STUDIES OF THE GREAT APES

The Fellowship will be awarded to an individual to facilitate the establishment of a long-term research project on a wild population of great apes. Preference will be given to studies with significance for understanding human origins and to those which explore the causes of variation in ape behaviour, particularly in previously unstudied habitats. The Fellowship will begin on October 1, 1984 and the award, worth up to $20,000, is for field expenses only.

Applicants should submit a curriculum vitae and one page statement of research goals by April 1, 1984 to the L S B Leakey Foundation, Foundation Center 1-7, Pasadena, CA 91125. Eligible candidates will be asked to provide further details by July 1. (NW244)E

INTERNATIONAL UNION OF BIOCHEMISTRY FELLOWSHIPS

for attendance at the 13th International Congress of Biochemistry

Amsterdam, The Netherlands, 25-30 August 1985

IUB and the Organizing Committee of the 13th IUB Congress will together make available awards to assist younger biochemists who wish to attend the Congress. Primary consideration will be given to residents of countries where the practice of the science of biochemistry is in the early stages of development.

The Fellowships will support part of the cost of travel (normally up to a maximum of half the listed economy air fare or 70% of the Apex fare, whichever is lower) and subsistence during the Congress. The Organizing Committee of the Congress will waive the registration fee for Fellowship holders.

Applications should include the following information:

1. Name and date of birth; 2. Citizenship, residence; 3. Place of work, including full postal address; 4. Nature of work; 5. List of publications; 6. Do you intend to present a contribution at the 13th Congress? If so, indicate its tentative title; 7. Support available or expected to be available to the applicant; 8. Names of three referees, one of whom should, if possible, not live in the applicant's country of residence.;

This notice should be shown to the referees, and applicants must ask them to write to Dr. R. L. Hill, at the address below, to reach him by 15 August 1984.

Applications must be made in triplicate and as early as possible, arriving no later than 15 August 1984, to Dr. R. L. Hill, Department of Biochemistry, Duke University Medical Center, Durham, North Carolina 27710, USA.

It is hoped to make known the decisions of the Selection Committee by 1 December 1984. (NW137)E

UNIVERSITY OF ABERDEEN

DEPARTMENT OF MICROBIOLOGY

TWO POSTDOCTORAL RESEARCH FELLOWSHIPS

Applications are invited for two postdoctoral Research Fellowships to join the group led by Professor W A Hamilton working on the role of sulphate reducing bacteria.

One post (ref Mic 1) financed by the SERC Marine Technology Directorate will be concerned with a study of corrosion processes associated with steel structures in the offshore oil industry, and will attempt to relate microbiological activities of biofilms with the electrical polarisation characterisation of naturally fouled steel surfaces.

A second post (ref Mic 2) is financed by BP Petroleum Development and is designed to strengthen basic continuous culture studies on the enzymology and physiology of growth of sulphate reducing bacteria on hydrogen.

Appointments will be from 1 March 1984 and will be for a minimum of one year at this stage.

Salary within range £7,190 to £8,530 per annum, with appropriate placing, within IA Scale for Research and Analogous Staff.

Further particulars and application forms from The Secretary. The University, Aberdeen, with whom applications (2 copies), specifying references no(s), should be lodged by 10 February 1984. (1019)E

QUEEN MARY COLLEG

University of London

APPLIED MATHEMATICS DEPARTMENT

Applications are invited for 1 or 2 year

RESEARCH FELLOWSHI

(with possibility of extension fo year). The core staff of the comprises 6 permanent membe the Academic Staff (Prof. Roxbu Drs MacCallum, Papaloiz Rowan-Robinson, Schwartz, Williams) while 4 other s members are engaged in rel research activities.

A Royal Society Research Fel several postdoctoral Assista visitors and research students are involved in the Unit, where rese interests span a wide range inclu solar and stellar physics, solar sy dynamics, interplanetary pla physics, interstellar mat extragalactic astrophysics cosmology, relativity gravitation. The Unit is also invo in the analysis of IRAS data.

Initial salaries in range £8,3 £10,161 pa (1 post may be at a senior level).

Applications, enclosin curriculum vitae, list of publicat description of recent and pla work and names of 2 referees, sh reach the College Secretary, Queen Mary College, Mile Road, London E1 4NS, by February. (1069

IIVERSITY OF READING

:PARTMENT OF PHYSIOLOGY & BIOCHEMISTRY

TWO RESEARCH FELLOWSHIPS

lications are invited for two post-toral University Research wships. The appointments will n the areas of (i) Molecular gy/Genetics: candidates should a background in molecular or atic cell genetics and should be rested in applying these niques to fundamental problems nimal growth and development mportance in agriculture. R2A).

leuropeptides: candidates should a background in the identifi-n and quantification of neuro-e peptides and an interest in ying these techniques to under-ding their role in neuro-crinology and neurophysiology. R3A).

ie Fellows will be expected to lop an independent research ramme within the structure of ting research groups. Both ointments will be for a fixed term hree years to start as soon as ible. Starting salary up to £9,425 SS superannuation.

pply, quoting appropriate Ref for application form to onnel Office, University of ding, Whiteknights, Reading 2AH. Further details can be ined in this way or by contacting R R Dils (telephone 0734 875123 600). (1055)E

IIVERSITY OF WARWICK POSTDOCTORAL FELLOWSHIP

lications are invited for a two postdoctoral fellowship to study nthesis and metal ion coordina-chemistry of new polyazamacro-c ligands. Salary on the Research ge IA scale: £7,190 — £11,615 pa.

or further details contact Dr P re, Department of Chemistry Molecular Sciences, University arwick, Coventry CV4 7AL. (1051)E

Atlas Research Fellowship

Pembroke College, Oxford University

The Rutherford Appleton Laboratory of the Science and Engineering Research Council in conjunction with Pembroke College, invite applications for a joint research fellowship. The aim of the Atlas Fellowship is to encourage studies, particularly those involving computers, in an area of research supported by the Rutherford Appleton Laboratory.

Topics include the following: study of condensed matter by scattering of neutron beams; some aspect of information technology including software engineering, IKBS, use of electron beam lithography in the fabrication of semi-conductor devices, image processing, computer aided design including electrical circuit design; finite element calculations; electro-magnetic systems; theoretical studies of the atmsophere and climate; remote sounding from space; image processing related to space astrophysics data reduction.

The successful candidate will be expected to undertake research work and have ideas on the programme he/she wishes to follow. Fellows have the rights and privileges of research fellows of Pembroke College, including the possibility of some teaching, and will be expected to spend the greater part of the time at Rutherford Appleton Laboratory.

There will be access to exceptionally powerful computer facilities, and our involvement with numerous university research groups gives an opportunity for contact with others engaged on a wide range of exciting research programmes.

The fellowship will be tenable for a period of three years and may be extended up to a period not exceeding five years. The stipend will depend upon the age and experience of the candidates selected, within the broad range £9,500 to £14,800.

For details of research fellows' rights at Pembroke College and application forms, write to Recruitment Office Personnel Group, Rutherford Appleton Laboratory, Chilton, Didcot, Oxon OX11 0QX, or telephone Abingdon 0235 445435 quoting reference No: VN 200.

The closing date for applications is: 17th February 1984 (1053)E

serc Rutherford Appleton Laboratory

UNIVERSITY OF READING

DEPARTMENT OF BOTANY

POSTDOCTORAL RESEARCH FELLOWSHIP

(Plant Cell Biology)

Applications are invited for a University postdoctoral Research Fellowship to investigate either gene expression during gametogenesis or molecular interactions involved in plant self-incompatibility mechanisms. Experience in cell biology is essential, and some familiarity with immunosystems would be advantageous. This fixed term, three year Fellowship will commence as soon as possible. Starting salary in range £7,190 — £9,425 pa plus USS.

Apply, quoting Ref R4A, for application form to Personnel Office, University of Reading, Whiteknights, Reading RG6 2AH. (1056)E

CALIFORNIA INSTITUTE OF TECHNOLOGY

POSTDOCTORAL FELLOWSHIP AT THE PALOMAR OBSERVATORY

A postdoctoral fellowship is available in the Astronomy Department, California Institute of Technology. The successful candidate will be expected to devote 50 percent of their time to work on the new Polomar Sky Survey which is to commence in early 1985. Duties would include: helping in establishing procedures for the survey; making observations for the Sky Survey for a few nights each month; quality control of the exposed plates. The Fellow would be expected to spend the other 50 percent of his or her time on science associated with the Survey. Applicants should have a good knowledge of astronomical photography and be familiar with some field of astronomy appropriate to the Survey.

The initial appointment is for 1 year, renewable for a further 2 years and starting October 1, 1984. The starting salary is $22,000. Applications should be sent by March 15, 1984 to: W. L. W. Sargent, Department of Astronomy 105-24, California Institute of Technology, Pasadena, CA 91125. Applications should include a curriculum vitae, bibliography of publications and preprints of manuscripts not yet published. Candidates should arrange for three letters of recommendation to be sent directly to Caltech.

Applicants will be considered without regard to race, religion, sex, national or ethnic origin, or non-disqualifying handicaps, in accordance with existing laws and regulations. Caltech is an Equal Opportunity Employer. (NW238)E

MAX-PLANCK-INSTITUT FUER ZUECHTUNGSFORSCHUNG COLOGNE

POST-DOCTORAL FELLOWSHIP IN MOLECULAR GENETICS

A post-doctoral molecular geneticist, preferably with experience in studying at gram-negative bacteria, is required to investigate the molecular basis of competition amongst rhizobium leguminosarium stains.

Position is available for a fixed term at two years beginning April, 1984 and carries a salary related to that at German Government employes.

Applications including a curriculum vitae, a full statement of research interests and experience, and the names of two references should be sent without delay to Dr. W. J. Broughton, Max-Planck-institut Fuer Zuechtungsforschung, D-5000 Koeln 30, FRG. (W685)E

CONFERENCES and COURSES

CHELSEA COLLEGE
(University of London)

MSc DEGREE IN BIOCHEMISTRY, IMMUNOLOGY, PHARMACOLOGY, BIOPHYSICS AND BIOENGINEERING

The following courses, leading to MSc by examination, will commence in October 1984.

MSc GENERAL BIOCHEMISTRY
2 academic years part-time (2pm-9pm, 1 day/week) or 1 year full-time. Candidates should be honours (first or second class) graduates in Chemistry, Pharmacy or a Biological Science, or hold a degree in Medicine or Veterinary Medicine.

MSc IMMUNOLOGY
2 academic years part-time (10am-5pm 1 day/week). Candidates should be honours graduates in a Biological Science, or hold a degree in Medicine or Veterinary Medicine.

MSc PHARMACOLOGY
1 academic year full-time. Candidates should be honours (first or second class) graduates in Science, Pharmacy or Medicine.
This course has been accepted by the SRC for the tenure of Advanced Course Studentships.

MSc BIOPHYSICS AND BIOENGINEERING
2 academic years full-time or 3 years part-time. Candidates should be honours graduates in Science, Engineering or Medicine.
This course has been accepted by the MRC for the tenure of Advanced Course Studentships.

For further information and application forms, write to the Secretary of the relevant department, Chelsea College, Manresa Road, London SW36LX. (1076)C

CHARLES COULSON SUMMER SCHOOL IN THEORETICAL CHEMISTRY

will be held at the Unitersity of Oxford from 9 — 19th September 1984.
The lecturers will be Dr. P. W. Atkins, Dr. D. L. Cooper, Professor N. H. March (Oxford) and Dr. N. C. Handy (Cambridge).
Further details and application forms can be obtained from Dr. P. J. Grout, Theoretical Chemistry Department, 1 South Parks Road, Oxford OX1 3TG.
Closing date for applications 1st June 1984. (1072)C

JAPANESE BIOTECHNOLOGY STUDY TOUR

An in-depth series of site visits, conferences and seminars with some of Japan's leading industrial scientists and executives in biotechnology.

This exclusive study tour is designed to give western scientists and executives an opportunity to become acquainted with the Japanese marketing and research capacity. The mission will be led by Christopher G. Edwards, Editor in Chief of BIO/TECHNOLOGY, and organized by the Technology Transfer Institute. Visits will be conducted throughout Japan from March 31–April 15.

For further information, contact: Technology Transfer Institute—New York, One Penn Plaza, Suite 1411, 250 W. 34th St., New York, N.Y. 10119. 212-947-2648 telex 420057TTIUI. Attention: Mr. Hashizume.

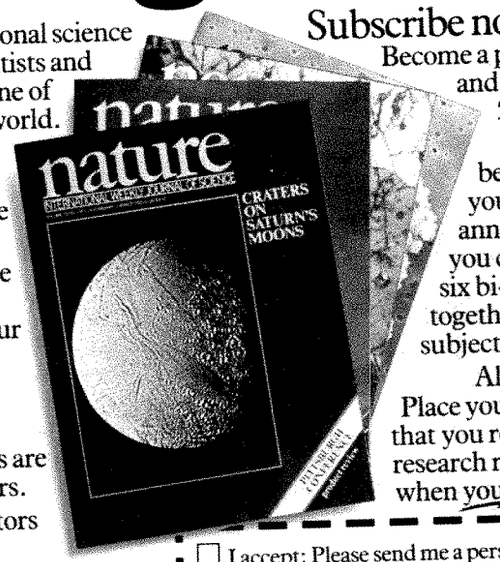
nature is keeping ahead. Are you being left behind?

research results, the very latest international science s, key papers by the world's leading scientists and d of publication ensure *Nature* remains one of oremost weekly scientific journals in the world.



But if you're tied in to a circulation list ork, all this vital weekly information will oubtedly reach you late, often incomplete sometimes not at all.

With your own personal copy, you solve roblem. Every week you'll have all the research results and science news in your is within days of publication:

- **s** reports from throughout the world of ce and technology.
- **ews and Views** section, where new ideas are sed and discussed by leading researchers.
- **les and Letters** in which key investigators ose their work for the first time.
- **Reviews** – Eminent figures offer expert judgments wide variety of recent publications.
- **ial Issues** providing an in-depth treatment of topics portance.
- **luct Reviews** – Detailed descriptions of laboratory oment newly available.
- **sified Advertisements** for a wide variety of positions er the world.

You will no longer be dependent upon other people down the 'list' copy, and because you will natically receive every issue, you won't risk missing le copy through absence from work. Moreover, you all this key information for permanent reference.

rough your door every week

Subscribe now – at Half Price

Become a personal subscriber now and you will receive a discount of 50% off the full rate.

All 51 weekly issues will be delivered to the address of your choice. You can start your annual subscription with any issue you choose. And you will receive six bi-monthly author indexes, together with the annual index of subject and author.

All this for just 94p a week.

Place your order now and make certain that you receive the scientific news and research results crucial to your work when you want them.

☐ I accept: Please send me a personal subscription to *Nature* for one year (51 issues) at the special half-price rate of £49.00.

☐ I enclose my personal cheque for £49.00 made payable to *Nature*. (Note: Institutional cheques cannot be accepted at this special rate).

☐ Please charge to my credit card account.

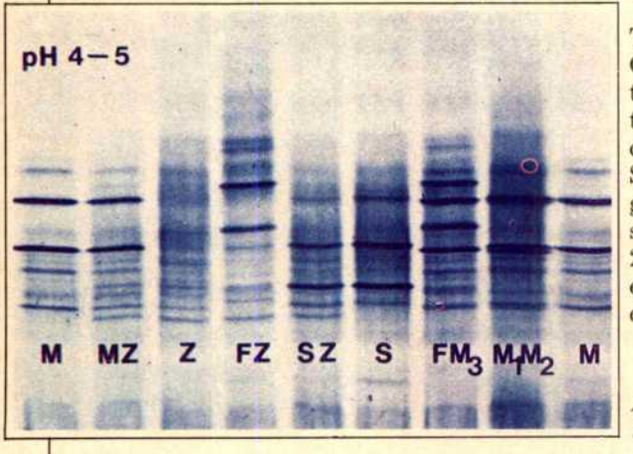
ION CHANNELS IN HUMAN T-CELLS



Only with the new LKB Horizontal

Unequalled flexibility i

READY-TO-USE GELS FOR MAXIMUM CONVENIENCE

All the owner of the LKB Horizontal Electrophoresis System needs to cover a wide range of electrofocusing applications is a supply of the popular and successful LKB Ampholine PAGplates. These allow the researcher to avoid the time and trouble involved in casting gels in the laboratory, while guaranteeing both high resolution and excellent reproducibility. As many as 96 samples can be separated simultaneously on a single PAGplate, enabling users with high workloads to spend their time screening samples instead of casting gels.

Eight phenotypes of α_1-antitrypsin are clearly identified using one of the convenient LKB Ampholine PAGplates ▼

ULTRATHIN GELS FOR MAXIMUM ECONOMY

Anticipating the need for less expensive electrofocusing gels, LKB developed the new UltroMould: a simple device designed to cast bubble-free gels as thin as 0.1mm in less than 30 seconds. Based on a patented sliding plate method, UltroMould is easy to use, producing perfectly accurate and uniform gels and ensuring a high standard of reproducibility. Adding UltroMould to the LKB Horizontal Electrophoresis System means that significantly less gel solution and smaller sample volumes are required, resulting in far more economical electrofocusing.

LKB UltroMould casts bubble-free ultrathin gels in only 30 seconds, making gel casting quicker, easier and more certain ▶

THICK GELS FOR MAXIMUM CAPACITY

Original electrofocusing techniques used thicker gels, and even today you may still wish to work this way in order to achieve higher capacity. The LKB Horizontal Electrofocusing System lets you easily cast and run Ampholine gels up to 2 mm thick, allowing much greater sample volumes to be analyzed successfully. The 2 mm thick gels are also ideal if you are new to electrofocusing and are following a procedure described in the literature.

After the thick gel has been cast, the sample is introduced with the help of the sample application foil ▶

This is one in a series of advertisements describing the unrivalled versatility of the LKB Horizontal Electrophoresis System. For further information about analytical electrofocusing, and the many other applications of the system, send today for our brochure.

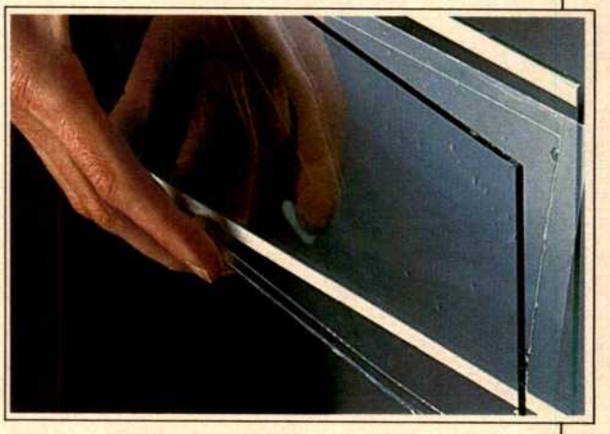
THE LKB SYSTEM

Only LKB can offer the research scientist a complete, integrated system in which each component works with and complements all the others. Based on the new and improved Multiphor II, the system also includes a 5KV power supply, thermostatic circulator, laser densitometer and data evaluation software.

In addition to the instrumentation, LKB provides a range of 18 major kits plus a complete programme of high quality chemicals, supplies and accessories, backed by the full worldwide support of the market leader in electrophoresis and electrofocusing.

LKB—the electrophoresis experts.

trophoresis System do you also get...

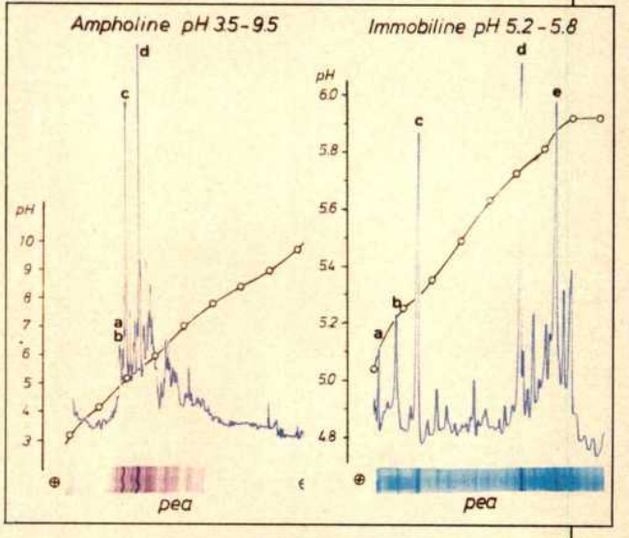


nalytical electrofocusing

AGAROSE GELS FOR MAXIMUM POROSITY

Another of the many options available to the user of the LKB Horizontal Electrophoresis System is the application of Agarose electrofocusing gels. LKB supplies extremely pure agaroses, carefully developed for electrofocusing, and the original capillary casting method simplifies the task of producing 0.5 mm gels on GelBond Film backing sheets. Agarose is non-toxic and easy to handle and the entire analysis procedure, including casting and running, is very rapid.

Separating the GelBond Film from the glass plate gives a 0.5 mm agarose gel, firmly attached to its support and ready to use ▶



IMMOBILINE GELS FOR MAXIMUM RESOLUTION

The unique LKB Immobiline System is significantly different to traditional gels in that its pH gradient is an integral part of the gel. The system is designed to allow the user to select a pH gradient as wide as 3.0 pH units, or as narrow as 0.1 pH units, anywhere in the range 3.6 to 9.5. This tailoring of the gradient to suit specific applications permits extremely high resolution to be achieved with the LKB Horizontal Electrophoresis System. Stable and reproducible linear gradients having a slope as low as 0.01 pH units/cm are possible, allowing you to separate proteins whose pI values differ by as little as 0.001 pH units.

Comparison of traditional electrofocusing and LKB Immobiline System (courtesy of Dr A Görg et al, Technische Universität, München) ▶

Circle No.50 on Reader Service Card.

Keep your copies of *Nature* protected in these tough black PVC binders

- Each binder is supplied with a set of wires for the easiest possible loading
- *Nature* logo blocked in gold on spine
- Transparent plastic pocket provided for your own reference
- Each binder takes two volumes of *Nature*; three binders will serve for a year
- Prices and address for orders are set out below

Annual Subscription Prices

UK & Irish Republic		£98
USA & Canada		US$230

Nature in Brazil

● Because of restrictions on foreign exchange in Brazil, the purchase there of international journals has become virtually impossible.

Nature is therefore introducing a scheme whereby scientists may purchase a year's subscription to *Nature* for a colleague in Brazil at half the usual price. Those wishing to take advantage of this scheme should write to either:

Felicity Parker
Nature
Houndmills
Basingstoke
Hants RG21 2XS, UK

Mirta Soto
Nature Publishing Co.
15 East 26 Street
New York,
NY 10010, USA

enclosing a cheque for $90.00 (surface mail) or $135.00 (airmail) or the equivalent in any currency, together with their full name and address and those of the intended recipient. Telephone orders may be charged to international credit cards. *Nature* will meet the extra cost of despatching the journal to Brazil.

This offer will remain open until 31 December 1984. The similar scheme to help Polish scientists continues.

Next week in *Nature*:

- Oncogenic determination of sequence for epidermal growth factor?
- Gene amplification by differently placed genetic inserts
- Albedo feedback and Sahel drought
- Solar conversion at 10 per cent efficiency
- More mantle inhomogeneity
- Pulsating stars for seeking gravitational waves
- Philip Gummett on *Government and Research* by M. Kogan & M. Henkel
- Sir Fred Hoyle reviews S. Chandrasekhar's *Eddington: The Most Distinguished Astrophysicist of his Time*

GUIDE TO AUTHORS

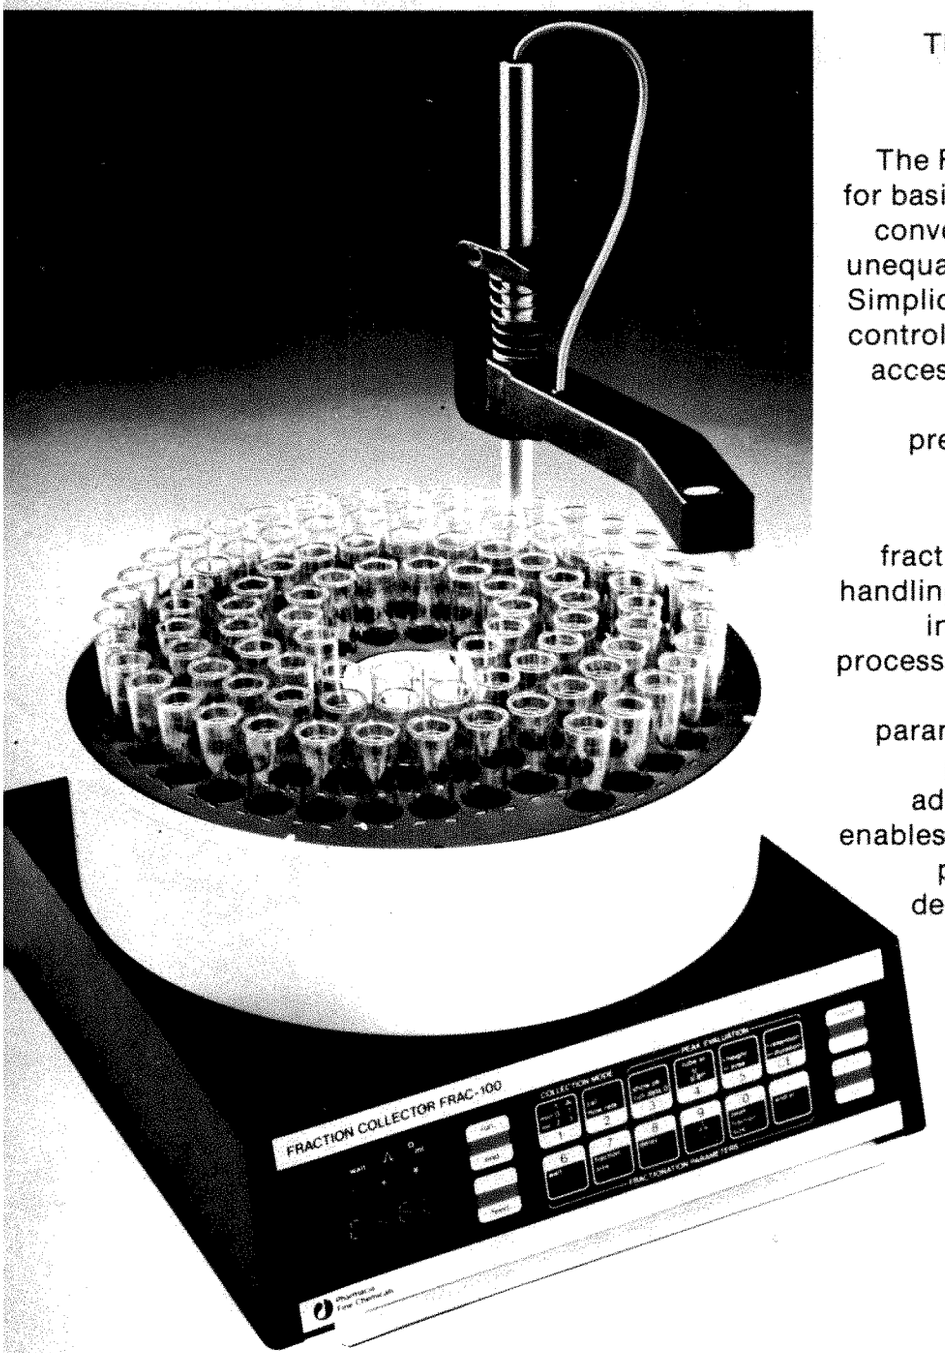
Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.



Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963–65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

The FRAC-100 *Fraction Collector*

The FRAC-100 does what any other small fraction collector does - collects fractions, PLUS .....

The FRAC-100 will fulfill all your needs for basic fractionation requirements. As a conventional collector the FRAC-100 is unequaled in performance and reliability. Simplicity in design (3 moving parts) and control (flexible fractionation parameters accessed by a multifunction key board) accomplish fractionation routines previously attainable only with large, expensive instruments.

The FRAC-100, as a sophisticated fraction collector presents unique data handling and integration capabilities. The input of a 0-10mV detector signal is processed by the FRAC-100 to report as a digital display such separation parameters as peak height, peak width, peak retention and peak area. The addition of a PSV-100 solenoid valve enables selective fractionation of only the peak material as judged by a slope detector defined by a programmable threshold value.

If what you're looking for is a small, simple, inexpensive fraction collector - the FRAC-100 is your best choice!

If what you're looking for is a small sophisticated collector with power and abilities far beyond anything presently available - the FRAC-100 is your only choice!

Does your fluorescent analyser keep you in the dark?

New from Coulter. The EPICS® C clinical flow cytometer analyses and sorts cells routinely on the basis of number, size and fluorescence by use of programmable protocols.
No fluorescent microscope analyses, no darkened rooms, no highly trained dedicated operators.

● differentiation of white blood cells (or any biological cells) ● fluorescence determination by specific antigen characteristics ● range of compatible monoclonal antibodies available (e.g. for T & B cell ratio, T helper/T suppressor) ● physical sorting of populations into sub-populations for further study ● high specificity allows previously inseparable cells populations to be determined ● automatic operation allows short 'half life' fluorescent determinations to be made.

Epics® C

Automatic cell analyser and sorter at an 'analyser only' price

Attention all biophysicists, molecular biologists and biochemists!

Biomembrane Structure and Function

Edited by
DENNIS CHAPMAN
Professor of Biophysical Chemistry
Royal Free Hospital
School of Medicine, London

Volume 4 in the TOPICS IN MOLECULAR AND STRUCTURAL BIOLOGY Series
Series editors:
Professor Watson Fuller, Dr Stephen Neidle and Professor Tony Atkinson

The application of physical techniques – such as X-ray diffraction and Raman spectroscopy – has revolutionised much of our thinking on the structure and function of membranes. In this important new study, contributors of international standing review a topical selection of approaches to the elucidation of **biomembrane structure and function.** The emphasis, throughout, is on the in-depth analysis of recent experimental work.

Published January 1984 Price £50.00 432pp
ISBN 0 333 31869 2

Contents

Calorimetric studies of model and natural biomembranes – *Diana Bach*, The Weizman Institute of Science, Israel; X-ray diffraction and electron microscope studies of the molecular structure of biological membranes – *Lee Makowski and Jade Li*, Columbia University, USA; Raman spectroscopy of lipids and biomembranes – *Surendra P. Verma and Donald F.H. Wallach*, Tufts-New England Medical Centre, USA; Infrared spectroscopic studies of model and natural biomembranes – *Ralph L. Amey*, Occidental College, USA and *Dennis Chapman*; Rotational and lateral diffusion of membrane proteins as determined by laser techniques – *Winfried Hoffman*, NUKEM GmbH, E.Germany, and *Colin J. Restall*, Royal Free Hospital, London; Theoretical models of monolayers, bilayers and biological membranes – *David A. Pink*, St Francis Xavier University, Canada; The Ca^{2+} dependent ATPase of sarcoplasmic reticulum – *G. Inesi and M. Kurzmack*, University of Maryland, USA.

Snapshot of a new industry

The much-awaited report to the US Congress on the international biotechnology industry may be flawed but it deserves to be widely read, not only in the United States.

THE US Congress, which commissioned the report on the international biotechnology industry published last week, should beware of the beguiling trap of chauvinism as it thumbs through the huge document that has now emerged (see page 402). For the Office of Technology Assessment (OTA), in the course of its patient description of who where is doing what, has unaccountably peppered an otherwise sober report with declarations that the United States has a "commanding lead" (in the development of software for the use of nucleotide-sequence data-banks) or is the "strongest in the world" (in its "efforts to commercialize biotechnology"). Few will dispute the validity of these and other assessments in the same genre, which in any case have the tactical advantage of telling Congress what it wants to hear. (Bearers of bad tidings are not much welcomed anywhere.) Moreover, these opinions bear directly on the chief conclusion of the report, that while "continuation of the initial preeminence of American companies in the commercialization of new biotechnology is not assured, . . . Japan is likely to be the leading competitor . . ."

The flaw in this jump from the particular to the general is not, of course, that it may be mistaken, for it is far too soon for anybody to tell, but that it is simplistic. OTA, which likes to be known as Congress's own think-tank, has let slip a splendid opportunity to read its masters a lesson in the economics of technological innovation and has couched its otherwise helpful answer in the outdated language of the 1950s (or even the 1930s). Indeed, the constant harping on the theme of leadership, by representing the process of technological innovation as a battle between two Goliaths, obliterates the texture of what is going on. In such an interesting field, there will be opportunities for all and, eventually, a division of labour, Adam Smith style.

Biotechnology may or may not be as old as lithofracture as a tool-making technology, but certainly dates back to the use of bacteria for turning milk solids into cheese and the use for other purposes of the liquids produced by the natural fermentation of fruit. So much, the report acknowledges in passing. In recent decades, the industry has gone up (with the use of fermentation techniques for making solvents in the 1930s) and down (with the advent of cheaper feedstocks from oil and natural gas). The novelty, in the past decade, is that techniques of genetic manipulation are certain to bring within the scope of traditional biotechnology the production of materials hitherto produced in other ways by, for example, the organic synthesis of pharmaceuticals.

Disappointment

Nobody doubts that the consequences will be important. Why else would investors in the United States and elsewhere have been so eager, in the past five years, to help launch new companies in this field? But the experience of the past five years has also shown that the new biotechnology differs in no substantial way from other new technologies, the development of steam engines in the second half of the eighteenth century for example. The immediate course of development abounds with disappointment — steam engines blow up, materials such as cloned interferon turn out not to be wonder drugs but chemicals in search of a disease to cure — yet confidence in the long-term future persists. The difficulty, in such circumstances, is that the pattern of the future is almost literally unpredictable.

The OTA report itself points to many of the potential sources of uncertainty — the likelihood that new biotechnology companies in the United States will find it harder to re-finance themselves when their original capital is exhausted, the high chance that even if things go well, many of them will have to rely on the sales organizations of established companies to ensure that their new products reach their intended users and the simple truth that vast areas of the potential of the new biotechnology are almost entirely unexplored. (Genetically manipulated plants that produce their own insecticides, for example, are a splendid and no doubt attainable goal but cannot yet be bred.) Short-term uncertainty against the background of long-term confidence should be the motto for the next few years. The question of whether the United States is "ahead", or whether Japan is a greater "threat" than any other industrialized country, is both irrelevant and dangerously misleading.

Clamour

If the new biotechnology is as important as it now seems, it will be important for decades to come and not merely for the lifetimes of the patents now being clamorously taken out. Moreover, if the opportunities for innovation span even a fraction of the ground now in prospect, there will be work enough to keep the technical communities of three continents (and perhaps even five) busy for decades to come. For the immediate future, of course, OTA is right to draw the attention of Congress to the reasons for thinking that the United States is an especially favourable place in which to embark on these exciting adventures — the availability of venture capital, the flexibility of the patent system (less is said about the problems that beset it) and the supply of talent. But the report enormously undervalues the way in which, in the long run, the emerging industry will be shaped by the unforeseeable application of unidentifiable people's ingenuity to the solution of practical problems by means that will not always yield intellectual property (as the saying goes) that can be protected.

The opportunity OTA has lost is that of reminding the US Congress that at the beginning of an industry capable of transforming the pattern of what now passes for industry, predictions of the future based on the extrapolation of the present are unsafe. What if, for example, several years of the accumulation of budget deficits on the scale made public this week should force the United States to follow other spendthrift governments along the paths that have undermined other people's entrepreneurial spirit? Or if the arrangements that have been made between industrial companies and universities turn out to be more distracting for the academics involved than the report considers likely? The danger, for the US Congress, is that while the OTA report will bring a good deal of comfort, it may also induce complacency.

What will be made of the document elsewhere? One thing is certain — it will be widely read. Governments elsewhere, but especially in Western Europe, will pay close attention to the argument that United States companies active in this field must chiefly fear competition from Japan, not Europe. On one point, they must agree with OTA: the flexibility of the system whereby new companies in the United States can be launched with the help of risk capital channelled through specialist financial companies is enviable, as is the arrangement by means of which investors may put money into specific research and development projects under-

© 1984 Macmillan Journals Ltd

taken by biotechnology companies in such a way as to ensure that gains are taxed as capital gains, not as income. European governments should also take to heart OTA's argument that the ease with which new companies can spring into existence in the United States, confusing though it may be for the stock markets, is a powerful spur to copious innovation and, perhaps more important, its rapid exploitation. It is, however, important to acknowledge that in the past two years, in Britain and West Germany, venture capitalism has been growing even faster than biotechnology. Whether the same governments will sanctify this trend with tax advantages comparable with those enjoyed in the United States remains to be seen.

By themselves, however, these differences do not explain why Japan should be distinguished from Western Europe as the ground in which biotechnology is more likely to flourish. Indeed, Japan (like West Germany until very recently) differs radically from the United States in that venture capital plays only a minor part in the capital financing of industry. OTA's argument is that several Japanese companies have admirable expertise in the exploitation of fermentation technology (which is true), that Japan is a huge market for pharmaceuticals (which is likely to be important in the short run) and that the Ministry of International Trade and Industry in Tokyo has launched a cooperative programme in biotechnology (which is less significant than OTA appears to think). Readers of the report will, however, conclude that OTA is most of all impressed at the number of Japanese companies that have declared their determination to prosper in biotechnology — and which are likely to turn their ambitions into reality with the zeal that has marked the success of Japanese manufacturers of automobiles and of electronic consumer goods. That is an awesome prospect but not a proof that European companies will be also-rans.

For those who would predict the future, one missing element in these calculations is the character of the relationship between the newer biotechnology companies and the larger companies with ambitions in the same field. OTA is probably right to guess that partnerships between big and small companies that already exist will often develop into even stronger relationships, outright mergers included. For large companies, which may have been slow to respond to the opportunities presented by biotechnology in the past decade, often enjoy the luxury of being able to bide their time, relying on their financial resources to be able to move quickly when the time is ripe. And once committed to the development of a new product, established companies have an advantage that newly established companies cannot but envy — an established and sometimes efficient mechanism for putting what they seek to sell into the hands of customers. Especially now that it has become plain that the benefits of biotechnology are further away than at first seemed possible, the large pharmaceutical and chemical manufacturers now operating on an international basis have powerful advantages over most newly created companies. None of this implies that there is no place for the smaller companies, nor even than none of them will grow big; indeed, OTA is entirely right to emphasize the value of the smaller companies as spurs to innovation in the past few years. But the growing importance of the multinational manufacturers in the development of biotechnology is yet another reason why pure chauvinism is out of place.

In the circumstances, the positive recommendations put forward by OTA are probably less urgent than they seem. OTA would have the administration reverse the recent decline of support for basic biological research (for which there are other good reasons) and do something unspecified to strengthen "bioprocess engineering" (for which there are few precedents). In strictly parochial terms, indeed, the threat that if Congress should fail to provide extra resources in those fields, the United States may lose its "commanding lead" to Japan or some other nation may be effective. It will be interesting to see how that issue is decided. Meanwhile, the chief value of OTA's gigantic study is that it has provided a unique snapshot of a new and important industry at a critical epoch in its growth, no longer neonate, still far short of puberty. □

Binary is divisive

Britain's system of higher education suffers from too little diversity and from being split in two.

FOR how much longer can the British system of higher education be allowed to continue as if it were two separate systems, one consisting of institutions called universities financed by central government through the University Grants Committee and the other consisting of institutions called polytechnics whose bills are paid by local authorities (with money provided by the central government)? The question has been in the air ever since the polytechnics were designated as degree-giving establishments nearly twenty years ago. The argument then was that there would be virtues in operating a dual system of higher education, if only because the newly established polytechnics could be guided, or coerced, to take a direct interest in the vocational needs of their students. It was almost as if the late Mr Anthony Crosland, the then Secretary of State for Education and himself once a university teacher, egged on by his Oxbridge civil servants, had washed his hands of the universities and decided that a quite different system would better serve the social need of higher education. In the event, the binary system (Mr Crosland's name for it) has not been much of a success. While many polytechnics have stuck admirably to their brief, and have won respect for their teaching and research in the process, others (there are twenty-six altogether) have aped the universities in the breadth of the curricula on offer, or have embraced unproved and therefore mischievous courses (admittedly fashionable in the 1960s) with elaborate titles such as "independent study", or have merely become dull. And sadly, both among academics and would-be students, the polytechnics are less eagerly sought after than are the universities.

Now, though, there is a chance that this may be changed. Guilefully, the Department of Education and Science has persuaded the universities that the system they operate for administering applications to enter universities from school students should also be used to administer applications for entry to the polytechnics. The scheme (whose cost will be met by the government) will operate for a trial period of two years, but everybody concerned insists that students wishing to hedge their bets on securing a place somewhere in higher education will have to complete two separate application forms, the data on which will be sedulously kept separate. This is either a nonsense or the thin end of a wedge, one that leads to a unified procedure for entry into higher education of either kind.

And not before time. Not merely young people looking for places in higher education but those who eventually employ them are thoroughly confused by the present system, which is a disgraceful monument to the corrosiveness of academic snobbery. Both types of institutions allow young and not-so-young people to earn degrees, whose authenticity in the case of the polytechnics is vouched for by an independent council. Polytechnics, it is true, lack people called vice-chancellors, and have directors instead. Senior teachers are called "heads of department", not professors. And they have courses in hotel management and catering as well as in Latin and Greek. But could all British universities justly claim that they are themselves so very different?

If not, university academics should follow the only honourable course open to them, and clamour for the abolition of the binary system by means of the abolition of the boundary between its two unjustly unequal parts. The opportunity will arise when they come to reply to the questionnaire put out last autumn by the still-new chairman of the University Grants Committee, enquiring in a neutral fashion about university opinion on the binary system. The practical benefits are obvious — students will no longer be quite as mystified, while more efficient use will be made of scarce resources. More important, however, the British system of higher education would at one swoop acquire the diversity of institutions only now being forced to emerge by financial deprivation. □

US defence research

Pentagon asks for stricter control of publication

Washington

THE Pentagon is seeking extensive new powers to change or block the publication of scientific papers written under Department of Defense (DoD) contracts. In a new policy directive (number 2040.2), DoD sets out a general policy for reviewing both basic and applied research carried out in academic settings.

Under the scheme, basic and applied research papers deemed not to be sensitive will have to be submitted to a DoD contract office at the same time as they are submitted for publication, although DoD will have no right to insist on changes or to block publication. Basic research characterized as sensitive will have to be submitted to DoD 60 days before it is submitted for publication. In these cases DoD will be allowed to suggest changes or recommend that publication should not go ahead, but the final decision will rest with the investigator.

Applied research papers which are sensitive will, however, have to be submitted to DoD 90 days before they are

submitted for publication, and DoD will be entitled to insist on changes in the manuscripts or to block publication altogether.

The new directive is part of an extensive Pentagon review of technology transfer which started in 1981 and is now nearing completion. As part of the review, six panels looked at research contracts, visa controls, emerging technologies, scientific conferences, publication and rules for exemption from the Freedom of Information Act. Their findings are being coordinated with those of a still secret interagency review of technology transfer started in 1982 after a National Academy of Sciences report called for an easing and simplification of existing controls on the publication of research with a bearing on national security.

The restrictions on publication proposed in the DoD directive are far stricter than those recommended by the academy's report, prepared under the direction of Dale Corson, former president of Cornell University. The main conclusion of the Corson panel was that too much secrecy in scientific communication would damage rather than strengthen US security because of its chilling effect on the scientific enterprise itself.

Warning that the effort to protect sensitive information was spread too thinly, the Corson panel proposed confining controls to a few "grey areas" where the technology was developing rapidly, had clear military applications and would, if released, give the Soviet Union a short-term military advantage it could not otherwise acquire.

DoD, however, wants to extend the scope of its controls. It suggests a looser definition of sensitive technology as that "perceived to have a military impact" and in which the Soviet Union is less advanced than the United States. Furthermore, DoD wants a new Militarily Significant Emergent Technologies Awareness List (METAL) to pinpoint frontier technologies that could be candidates for stricter controls.

DoD's break with the Corson recommendations has come in spite of a formal improvement in liaison with the universities. Twenty academics have been invited to join an academic advisory group for Comex, the committee on exchanges which recommends whether scientific visitors from unfriendly nations should be granted visas. A government/industry/university research round table has been established within the National Academy of Sciences but has not yet met. And a working group on export controls, attached to the DoD/University Forum, has given the academic community periodic progress reports on the Pentagon's internal review of scientific controls.

The complexity of the existing control mechanisms continues, however, to baffle both scientists and officials. For example, an extension course on materials science held recently at the University of California, Los Angeles (UCLA), was barred to foreign citizens. Michael Bley, UCLA's director of marketing, said some of the technologies to be discussed were on the US Munitions List. But he admitted that publicity for the course had not mentioned that citizens of the United Kingdom, Canada, Australia and New Zealand would have been able to attend under the terms of a technical cooperation agreement with the United States.

Publication, if it is ever declassified, of the interagency study on technology transfer may clarify the issue. The DoD study, however, gives little cause for optimism. From the point of view of the universities, its only welcome recommendation is the creation, for the first time, of a technology transfer appeals board within the Pentagon. Otherwise, its recommendations are far more conservative than Carson had wished.

Peter David

Ariane launch delay

Europe's hands clean

THE launch of Ariane, Europe's hope of an answer to the space shuttle, is suffering from greater and greater delays, just as the shuttle is getting into its stride.

For once, however, the problem is in the United States. Ford Aerospace in Palo Alto, California, is desperately trying to remedy a fault discovered in the Intelsat V (F8) series of communications satellites, one of which was due to have been launched by Ariane last November. Neither Ford nor the European Space Agency (ESA), administratively responsible for launching the satellite from its Kourou (French Guyana) base, will commit itself to a date more precise than "the end of February". Only two weeks ago, the canvassed launch date was mid-February.

The problem — interference on an L-band maritime communications system attached to Intelsat Vs from the fifth onwards — is "intermittent", says Ford. This may be taken as a code word for almost impossible to reproduce.

The Intelsat organization has leased these L-band systems to London-based Inmarsat, which deals solely in ship communications, and Intelsat will suffer penalties if the systems do not work. Equally, however, the organization faces penalty clauses in the contract with ESA, if launch is delayed too long. But, according to an ESA official, relations with Intelsat have not deteriorated to that stage yet: "we are not thinking about it", said the official.

According to ESA, if Intelsat V (F8) does get away by the end of February, there will still be five Ariane launches this year. But this compares with as many as eight foreseen last May and with ten scheduled shuttle launches. The next 18 or so satellites to be launched in the Ariane series, some in multiple launches with the more powerful Ariane-3 launcher, are all communications satellites, the first novelty coming with the high-resolution French SPOT remote sensing satellite, now due to be launched some time in mid-1985.

OTA biotechnology report

Congress told US ahead, Japan second, rest nowhere

Washington

PREEMINENCE in the life sciences, abundant venture capital and an entrepreneurial spirit have combined to give the United States a commanding lead in the commercial application of new biotechnological techniques, although Japan will pose a growing challenge. That is the conclusion of a 612-page study of the international biotechnology industry published last week by the Office of Technology Assessment (OTA), Congress's science think tank.

The report, *Commercial Biotechnology: An International Analysis,* predicts that within the next 5–10 years a range of new biotechnological products — including pharmaceuticals, animal vaccines and speciality chemicals — will reach the market. Europe is lagging behind the United States and Japan but a few big chemical and pharmaceutical companies in Britain, France, West Germany and Switzerland may compete strongly in the manufacture of some products.

OTA ascribes the US lead to a number of factors, notably its uniquely favourable tax climate. In 1983 alone, the private sector invested more than $1,000 million in the commercialization of biotechnology in the United States, and since 1976 more than 100 new biotechnology companies have been started up with private venture capital. Underpinning this effort is an enormous investment by the federal government in basic research in biotechnology — some $500 million a year compared with about $60 million each by Japan, Britain, France and West Germany.

Ready access to venture capital has given the biotechnology industry in the United States a different structure from that of other countries. While its main competitors have depended for the commercialization of biotechnology on established companies, the US effort has been strengthened by a profusion of embryonic companies that have sharpened competition and hastened the spread of expertise from the universities.

But the US lead is not unassailable. OTA believes Japan could catch up if the United States continues to prune funds for basic research in the life sciences and to neglect applied research and bioprocess engineering — the skills that take novel production techniques the laboratory to the factory. Japan has more bioprocess engineers than the United States and spends a bigger slice of its science budget on the solution of applied research problems. Its knack of beating other countries in the race to apply their own basic research could, says OTA, give Japan a bigger share of the biotechnology market than the United States.

What accounts for the United States' present lead? The report says the three most important factors in the competition to commercialize biotechnology are the financial and tax incentives provided by governments, the amount they invest in research and the degree to which they ensure that there are enough well trained experts. In all three areas the United States scores higher marks than its competitors but it cannot afford to be complacent.

The big postwar investment in the basic life sciences has given the United States a competitive edge in the supply of molecular biologists and immunologists, but there may not be enough plant molecular biologists and scale-up experts. Japan, Britain and West Germany, unlike the United States, have invested steadily in generic applied microbiology and bioprocess engineering, areas which will become increasingly important as the industry turns from its present fascination with research and development towards the manufacture of products.

OTA also adds a warning that the dynamism of the newly created biotechnology companies cannot be taken for granted as the industry matures. The existing division of labour between the small companies that have pushed ahead fastest in research and the established companies that have concentrated on marketing and production may break down as the larger companies do more of their own research. And many of the new companies may be unable to raise the money they will need in 5–10 years to move from research to production.

OTA expects the real test of US competitiveness to come when large-scale production begins and bioprocess problems must be faced, initially in pharmaceutical markets. Here the United States will face impressive competition from both Japan and Europe. OTA notes that Britain's major pharmaceutical companies — such as ICI, Glaxo and Wellcome — have a great deal of expertise in bioprocessing and that Britain conducts some of the strongest basic research in interdisciplinary plant sciences.

Japanese companies, spurred by government "targeting" of biotechnology, have launched a new drive to enter international pharmaceutical markets. Japanese companies are already world leaders in large-scale plant tissue culture, and the Ministry of International Trade and Industry (MITI) has identified secondary compound synthesis from plants as a major area for commercialization. Unlike the United States, Japanese industry is investing heavily in research on speciality chemical production, an area where Japan is already prominent. **Peter David**

Europe

OTA's slight resented

THE Office of Technology Assessment (OTA) report on world biotechnology seriously underestimates Europe's potential, specialists at the European Commission in Brussels were saying last week. "The report puts Europe firmly in third place, with Japan the only competition for the United States", but this overlooks the quality of basic research in Europe according to one official.

Another critic, Dr Mark Cantley, who for two years headed a team investigating the future of biotechnology in Europe as part of the Commission's FAST (Forecasting and Assessment in Science and Technology) investigation, and who is listed as a contributor to the report, says that the last version of the OTA report that he saw was "a relatively messy document", uneven in quality.

A sense of umbrage about the report has been building up in Europe since nearly a year ago, when drafts of the final version first became available. It seems that many European governments were able to persuade OTA to incorporate last minute assessments of the state of biotechnology in their countries. The difficulty seems to have been OTA's reliance on published documents and reports from national contributors rather than on first-hand investigation.

Cantley nevertheless says that OTA is correct in its political judgement of the "difficulty of getting our act together". He illustrates this with the problem of isoglucose in Europe, where a cheap enzymatic method for producing the sugar was effectively vetoed by the sugar-beet lobby. One of Cantley's hopes for the future is that it may be possible to bring about a better integration of agricultural and industrial policy so as to remove impediments to innovation in the agricultural field.

One of Cantley's colleagues, Ken Seargent, noting OTA's dismissivenes of Europe, nevertheless insists that "it need not be like that". He cited both the potential of research in the natural sciences and practical successes such as the pyrethrin analogue insecticide developed in Britain.

Meanwhile, in Brussels, officials were hoping earlier this week that the Commission would agree on Wednesday 2 February to establish a "concertation unit" in biotechnology as a catalyst for more European cooperation in the field. Research commissioner Etienne Davignon is thought to consider this step so important that he will find the money (roughly $1 million a year) from within his existing budget, thus avoiding reference to the strife-torn Council of Ministers.

Some in Brussels even consider the new unit as the foundation stone of a European

0028-0836/84/050402-01$01.00

policy on biotechnology as ambitious as the information technology policy embodied in the Esprit programme still awaiting political approval and financial blessing. In the meantime, however, the concertation unit would establish and maintain a network of experts, strengthening the present arrangements for coordination on biotechnology among the ten member states. **Robert Walgate**

Finance

Small companies star

ONE theme running through the Office of Technology Assessment (OTA) report is the importance to US biotechnology of the newly formed specialist companies of which more than 200 are listed in the report. OTA says that these appear to be more productive of research-based innovation than established companies when compared person for person, and that they have a tendency to bring research results to the market more quickly than better established companies. The report notes, however, that newly formed companies, launched with private funds or by means of a public offering, may find the problems of refinancing more difficult when their initial capital is used up, if only because investors in new companies necessarily look for good returns. This opinion appears to have been written before the onset of the fall in the value of biotechnology stocks last autumn.

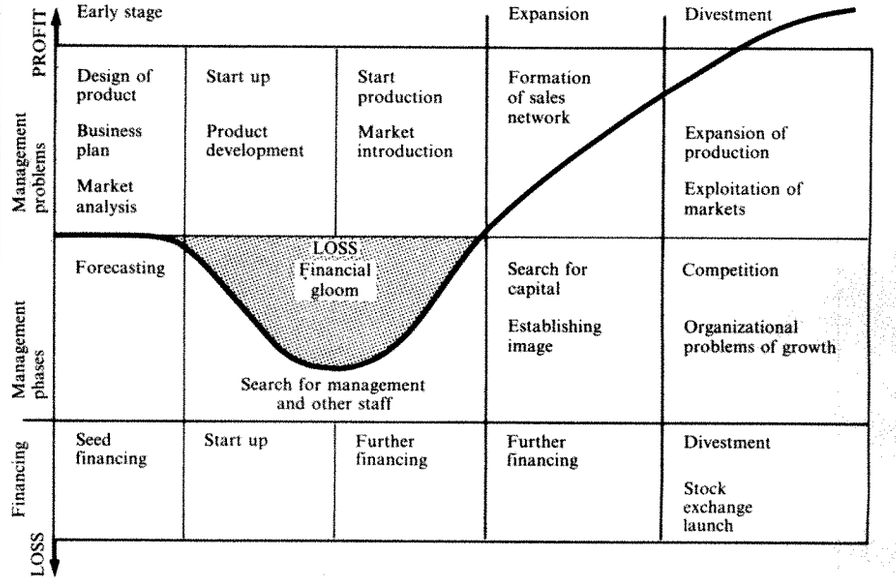
In an analysis of 18 US biotechnology companies whose shares are publicly traded, OTA points out that only three (Cetus, Genentech and International Genetic Engineering) had positive earnings in the latest complete financial year and that two of these were in that happy position because of interest earned from funds obtained in public offerings. OTA notes that the high cost of financing research programmes has persuaded many companies to finance their operations through research contracts with larger companies or to recruit capital by means of limited partnerships in respect of research and development projects. For similar reasons many companies are giving priority to the development of products that will have an immediate market, such as monoclonal antibodies for the diagnosis of disease and veterinary products and feed additives for livestock.

In spite of the publicity given to biotechnology, OTA points out that venture capital is still flowing more strongly into the fields of communications, computers and electronics, which consumed nearly 60 per cent of investments in 1982. One striking feature of the pattern of investment in the past few years has, however, been the willingness of established US companies to invest in their smaller brethren. In 1982, the total investment in new biotechnology companies from this source is estimated to have been $120 million but to have fallen to $40 million in 1983, chiefly because of the increasing attention paid by the larger companies to strengthening their own in-house activities.

Looking ahead, OTA says that new companies may ultimately suffer from these arrangements because of the low profit margins to be expected from patent royalties, the chance that research contracts will not be renewed and the willingness of the larger partners in research contracts to devote resources to the exploitation and marketing of new products. For these reasons, OTA concludes, successful biotechnology companies will in due course find it necessary to engage in the whole range of activities bearing on the exploitation of their innovation.

On the links between universities and industrial companies, new or well established, OTA notes that there are advantages for both partners as well for the "national innovative process". At the same time, it points out that universities cannot expect that royalty income from patents will ever be a substantial part of their current costs. On the basis of a questionnaire sent out to university administrators, teachers and students, OTA comes to the conclusion that the reduction of federal funds for universities has been a spur, that few difficulties have arisen in the conduct of these relationships, and that 85 per cent of respondents considered that links with industry had not damaged university research. □

West Germany



More adventure from capital

OBSTACLES to technology transfer and the formation of new companies in West Germany could be swiftly removed if a motion tabled in the Bundestag by two parties of the government coalition (the Christian Democratic Union, CDU, and the Free Democratic Party, FDP) is adopted. The need to improve the position of small and medium-sized companies in the Federal Republic is confirmed by the dim view of European investment in biotechnology taken by the US Office of Technology Assessment (OTA) (see page 402).

Although the stock market recently reached an all-time high and West Germany is still a leading world exporter, its share of world trade has fallen. Except for a few traditional areas such as chemicals, automobiles and electronics, the country has become an importer of high technology. More companies are going bankrupt than are starting up whence the interest in the search for means to encourage the formation of new high technology companies.

A major part of the problem is recognized to be the dependence of West German industry on loan capital rather than equity (risk) capital, which at present accounts for only 20 per cent of the capital employed by public companies, with a mere 5 per cent representing savings by members of the public. The banks, the main source of capital and the only insti-

Profile of a company start-up by venture capital

VENTURE capitalism combines financing with management and technical expertise. The investors take an active role in the development of the company. Misjudgement, takeover, merger or loss of crucial staff are a few "risks" that would give a different profile. A successful investor can hope to see this picture emerge for one third of his ventures; one third would level off to a low profit; one third would be written off. A reasonable time would be five years. □

© 1984 Macmillan Journals Ltd

tutions allowed to launch companies on the stock market, have been reluctant to support ideas and technological expertise alone, preferring more tangible bricks-and-mortar propositions. In addition, high taxes and charges discourage companies from flotation on the stock market and make equity capital more expensive than bank finance. It is estimated that this has created a DM100,000 (£25,000 million) "equity gap". In 1984, some 600 new companies will probably be launched on the US stock exchanges, whereas in West Germany, if the present situation continues, there will probably be no more than 20 new arrivals.

The lack of venture capital, the power behind the technology transfer represented by Silicon Valley and US biotechnology, is acute in West Germany. Yet in the United States since 1970, venture capitalists in 600 firms have invested a cumulative total of more than $8,000 million and have, in the process, created more than 600,000 jobs. Fifteen per cent of this capital has come from abroad and an optimistic estimate is that some DM 100,000 million could be available in West Germany if the right investment framework were created. Citicorp, experienced venture capitalist of the New York Citibank, is planning to invest DM420 million in Europe, including DM 140 million in West Germany.

Home-grown steps in this direction have also now become apparent. Apart from the Wagnisfinanzierungs GmbH, founded by a grouping of 29 banks, the most significant venture fund in West Germany has been started by Siemens under the name Techno Venture. The fund is capitalized at DM130 million, of which Siemens has contributed DM20 million and DM70 million has come from within West Germany. Private groups administer other funds, a small community has launched a fund through its local savings bank and the city of Berlin has begun a DM10 million fund. Minister of Research and Technology, Dr Heinz Riesenhuber, himself a successful businessman has advocated that 0.1 per cent of institutional funds should be used as venture capital.

Dr Riesenhuber emphasizes the need to create the right framework for research, technology transfer and commercialization, rather than direct state support and direction.

In the United States last year, it is estimated that 32 per cent of venture capital funds were contributed by pension funds, 32 per cent by insurance companies and 21 per cent by industry and foundations. Other financial routes such as tax-favoured research and development partnerships also exist to channel private funds into US industrial growth points. The OTA report concludes that "the unique complementarities between established and new firms, the well-developed science base, the availability of finances and an entrepreneurial spirit have been important in giving the United States its present competitive advantage in the commercialization of biotechnology . . . the (European countries) lag behind because they generally do not promote risk-taking, either industrially or in their government policies." The CDU/FDP motion is one step towards correcting this.

Sarah Tooze

Technical innovation

Plea for UK tax-breaks

THE British treatment of scientific research and patenting costs for taxation purposes is anomalous and may be inhibiting research and innovation in Britain, according to a report published last week by the Technical Change Centre. The report, written by a former senior economic adviser at the Inland Revenue, concludes that there is a powerful case for a more favourable tax treatment of research, which would be helpful to progressive industrial companies and would cost no more than £80 million in its first year.

The Technical Change Centre, which is supported by the Leverhulme Foundation, the Science and Engineering Research Council and the Economic and Social Research Council, produced studies on a variety of subjects, linked by the common theme of technical change. Its examination of the tax treatment of intellectual property in Britain finds that Britain gives highly favourable treatment to capital expenditure on plant and machinery compared with that on patents and know-how. As things stand, capital expenditure on patents in Britain is written off over 17 years and expenditure on know-how over 6 years. The specific proposal examined is that expenditure should be written off as it is incurred, like that on plant and machinery. This would, it is argued, restore some of the advantages once enjoyed by research that have now all but disappeared.

The report considers a number of possible objections but does not find any of them conclusive. Some, like the probable need for more civil servants in the Patent Office to cope with the likely increased number of patent applications, are dismissed as only "debating points", while others, such as the objection that companies might make increased use of patents as marketing gimmicks, are considered to be small risks.

On the positive side, it is concluded that the total cost of the scheme would be justified to the public by its immediate benefit to the more technologically progressive firms that are thought to be essential for Britain's future economic prosperity. While the cash flow of industry as a whole would not be affected to any significant degree, there would be a strong incentive to licensees to acquire patents if their costs could be written off immediately.

Tim Beardsley

China's research

Call to go back to basics

CHINA'S minister in charge of the State Scientific and Technological Commission, Mr Fang Yi, has spoken out firmly in favour of basic research as the foundation of the future scientific and technological development of the country. Addressing the fifth session of the scientific council of the Chinese Academy of Sciences recently, Mr Fang Yi noted that because major technological advances will become more and more dependent on breakthroughs in basic research, "some foreign countries" will be less willing to publicize their basic research in the open literature. China should therefore pay ever more attention to fields of basic research that will "open new paths" for technological development.

Mr Fang Yi's remarks differed considerably in emphasis from other recent official statements which put greater stress on the importance of applied research for the development of the Chinese economy, although he did note that particular emphasis should be given to "those fields of basic research which could have significant effects on the long-range development of the national economy". Current guidelines specify these fields as information science and technology, biotechnology, lasers, nuclear technology, computers and marine engineering.

As far as "big science" is concerned, with its demands for "enormous human, material and financial resources", Mr Fang Yi said that China's "limited conditions" imposed a need to be selective and to carry out only a few projects "according to our capabilities". Once a project is approved, however, scientists should be left to work in peace, since basic research demands "long-term efforts" and a tranquil atmosphere in which scientists can work in a "steady and sustained manner".

Mr Fang Yi's remarks seem intended as a not-too-veiled criticism of the attitude which still pervails in China as an aftermath of the cultural revolution and which is highly critical of the value to the economy of "intellectual" work. (Cases have been reported during the past year of misguided party activists criticizing the payment of bonuses of a few hundred yen to engineers and designers whose innovations have produced a very much larger financial gain.)

At the same time, even the Chinese Academy of Sciences will not have an entirely free hand. It must, Mr Fang Yi said, "show an adequate division of work and foster close cooperation with industrial departments, universities, national defence research departments and local research centres". In the applied sector, the Academy of Sciences must carry out research "more farsightedly, sooner and more intensively" than these other bodies.

Netherlands energy policy

More wind in prospect

Waalre, The Netherlands

AFTER two years, during which some 42,000 people took part in discussions throughout the country, great public debate in the Netherlands on energy policy has finally ended. But for the politicians, for some of whom the debate has conveniently postponed difficult decisions, the argument is only now beginning.

Predictably, the consensus reached in the final report on the debate favours much greater efforts in conservation and greater use of renewable energy. There is a need for the continued use of coal, the report concedes, but it comes out against the idea of any new nuclear power stations.

About Dfl 28 million (£6.3 million) has been spent on the two-year consultation exercise, of which Dfl 8.5 million went on 63 information projects (brochures, exhibitions and so on) and 14 research projects (energy analysis of nuclear power, for instance). A nine-member steering committee was set up in July 1981 under the chairmanship of the then minister for higher education and science policy, M. de Braauw. The committee had a scientific staff of 14 and an administrative staff of 16.

The idea for a public debate on energy came originally from the largest of the Protestant churches, with support from the largest labour union. In 1980, a parliamentary decision was made to embark on the public debate, providing a forum for the heated discussions that followed the abandonment in 1976 of a plan to build three nuclear power plants. Ironically, that plan had been put forward by Ruud Lubbers, then minister for economic affairs, who is now prime minister.

The first reactions to the report from the electricity producers are hostile. Public feeling against new power plants using fossil fuels is sustained by the knowledge that at present the Netherlands has a 50 per cent surplus of electricity generating capacity (the total is now 16,000 MW). After 1992, however, new capacity will probably be needed to replace obsolete plant. The report calculates that a "decentralized capacity" of 8,000 MW is feasible — 2,500 MW as wind power and 5,500 MW as combined heat/power in industry and city heating systems. In the past few weeks the electricity producers have been lobbying for more nuclear power, but to little avail.

In condemning nuclear power, the report stressed the problem of disposal of nuclear waste in a country as densely populated as the Netherlands. Supporters of nuclear power have concentrated on the high cost of electricity in the Netherlands compared with that in neighbouring countries such as West Germany and France. The steering committee claims, however that costs in France are kept artificially low by large government subsidies.

Environmentalist groups have naturally welcomed the report's conclusions, but whether any action is taken will depend on the politicians. And as the present policies of the three main political parties are not in line with the outcome of the public discussion, it may be a long time before Dutch energy plans for the 1990s are known.

Casper Schuuring

It's an ill wind. . .

THE following exchange took place in the British House of Lords on 23 January. Lords Paget and Cledwyn are members of the Labour Party, Lord Trefgarne is an under secretary of state in the Ministry of Defence.

Lord Paget of Northampton: My Lords, does not the noble Lord the Minister feel that all these questions are along the wrong lines? *Homo sapiens* has launched upon a career in which he is numerically doubling himself every 30 or 40 years. He is plainly in need of a massive cull. Nuclear weapons will make possible that massive cull — and, even more, they have the special factor of muddling up the genes so that from the new crop, something rather better than the present lot may emerge. Ought we not look to our good fortune?

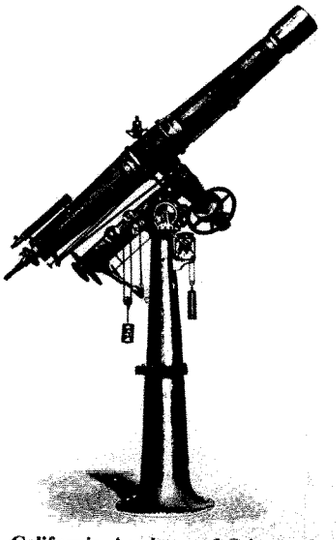
Lord Trefgarne: My Lords, the originality of the noble Lord's views never ceases to impress me.

Lord Cledwyn of Penrhos: My Lords, is the noble Lord the Minister aware that what my noble friend has just said is not Labour Party policy? □

Polish science

Academy's position compromised

THE Polish Academy of Sciences has experienced some difficulty in the election of a new president, and many academy members see this as an indication of increased government and party supervision of the academy. Unlike most socialist countries, Poland has no effective analogue of the Soviet State Committee for Science and Technology, so the academy plays a major role not only in basic science but also in the coordination of applied research. The academic secretary of the academy holds ministerial rank, and reports directly to the prime minister. During the liberalization of 1980–81, there was pressure within the academy to make the academic secretary responsible to the academy members.



The promised new legislation on the academy is said still to be in the preparation stage, although it will almost certainly differ considerably from the hopes of the Solidarity period. In the meantime, Dr Aleksander Gieysztor, a historian, who was elected president in the early days of Solidarity, came to the end of his three year appointment, and was due to retire or stand for re-election in December. Party officials responsible for scientific matters thought Dr Gieysztor's reelection would be a hindrance to closer ties between the Polish academy and the academies of other "friendly" (that is socialist) countries, and he was urged not to stand for re-election.

The party's own choice for president was Dr Leonard Sosnowski, a solid state physicist, who is personally popular with many academy members. In the first round of academy elections in December, however, Dr Sosnowski was roundly defeated in the secret ballot. It seems likely that some voted against him on the grounds that they did not wish to be "manipulated" by the party, while others felt that, without casting any aspersions on Dr Sosnowski himself, it was unwise on principle to elect as president a party member, because this might give rise to a conflict of interests if the academy found itself opposed to party policy.

The second round of voting last week, however, resulted in a clear winner, Dr Jan Karol Kostrzewski, an epidemiologist and a vice president of the academy, of whom little appears to be known — except that he is not a party member.

Vera Rich

Spare parts wanted

THE California Academy of Sciences in San Francisco is appealing for help in its search for spare parts for the 6.4 inch telescope installed in 1879 at what was then the city's first observatory. Access to a similar telescope would allow the missing parts to be replicated.

The instrument was constructed by the Fauth Company and the mounting may even have been the first of that company's model 72 to have been built. Those who know of the whereabouts of a telescope of this construction are asked please to contact Allan Wilson at the California Academy, Golden Gate Park, San Francisco, California 94118. Collect calls will be taken. □

Genetic manipulation

British watchdog reconstituted

BRITAIN's Genetic Manipulation Advisory Group, known as GMAG (pronounced Gee-mag with the first syllable as in "genome"), met for the last time last week. The group is to be replaced by a new body, the Advisory Committee on Genetic Manipulation (ACGM), which will give advice on safety aspects of recombinant DNA techniques to the Health and Safety Commission, an independent body charged with devising policy on occupational safety for implementation by the Health and Safety Executive.

The formation of ACGM was announced in the House of Commons by Mr Peter Brooke, Under Secretary of State in the Department of Education and Science, under whose aegis GMAG operated. Like GMAG, the new body will have representatives of employers' and employees' organizations as well as technical experts. Unlike GMAG, however, ACGM will have no representatives of "the public interest". The new committee, whose membership has not yet been announced, will be concerned with policy matters, leaving the scrutiny of individual experiments to officials.

There has been a growing consensus that work involving genetic manipulation holds fewer hazards than was at one time feared, and so GMAG's role has become correspondingly less important. It would have been disbanded before now but for the delay in setting up a parallel body, the Advisory Committee on Dangerous Pathogens, itself caused chiefly by an outbreak of smallpox infection at the University of Birmingham in 1978. The government seems to have decided that it would be politically inappropriate to do away with GMAG while the pathogens committee was being reorganized.

ACGM will take more of a back seat than did GMAG. GMAG members, many of whom will serve on the new committee, have, however, been told that the new committee will be free to initiate action and to plan its own work. The decision to hand over the day-to-day business of keeping records of recombinant DNA research to the Health and Safety Executive was fully approved by GMAG members, although some working scientists doubt whether the change will make their lives easier. Most say they were content with the way in which GMAG carried out its duties in recent years, since the levels of containment required for most work have been reduced and notifications of routine work can now be made retrospectively. In future, scientists will have to deal with officials of the Health and Safety Executive who may be less easy to please than GMAG.

The new committee has been given by GMAG a list of several urgent topics for discussion, including commercial confidentiality, the release of genetically engineered organisms into the environment and work with oncogenes. Despite industrial scepticism at the outset, GMAG seems to have been able to assure commercial companies of confidentiality; now, doubts have arisen whether the constitution of the Health and Safety Executive, which includes provision for the disclosure to work-people of companies' plans, will allow this guarantee to be continued.

British opinion on the release of genetically-engineered organisms into the environment, recently a source of controversy in the United States (*see Nature* **305**, 564; 1983), is likely first to be tested by research at the John Innes Institute in Norwich. Work with *Rhizobium* bacteria, which fix nitrogen in legumes, holds the promise of allowing the host specificity of different species to be altered, when the efficiency of nitrogen fixation might also be increased. Before approving field trials, ACGM will have to be sure that an experimental organism could not compete with wild types or, alternatively, could be destroyed if necessary. One fear is that host growth could be inhibited: disablement of legumes with a selected strain of *Rhizobium* has already been demonstrated and an engineered strain could conceivably be an effective pathogen. And the committee is asked to note the growing evidence that some human oncogenes linked to particular promoters may function like animal tumour viruses.

While nobody doubts the competence of the new committee to tackle these issues, another question remains: who will be responsible for considering ethical problems that may arise with genetic manipulation techniques? The government's Warnock committee, which is expected to report in the summer, is considering these questions as they relate to human fertility, but some members of GMAG want to see more permanent provision made. The issue is so far unresolved. **Tim Beardsley**

European air pollution

UK inspector protests at Brussels

SHOULD air pollution controls in Britain be tightened in order to combat acid precipitation? The latest body to enter the debate is the Industrial Air Pollution Inspectorate. In the inspectorate's annual report published this week*, the chief inspector, Dr Leslie Reed, inveighs against the use in legislation of emission limits such as those planned in two European Commission proposals for Community directives. Dr Reed will be giving evidence on the European air pollution proposals next week to the House of Lords' European Communities committee.

The cornerstone of British air pollution control since the first Alkali Act was passed in 1863 has been the statutory requirement that operators of scheduled plant should employ the "best practicable means" to control emissions. The chief industrial air pollution inspector, who was until recently known as the chief alkali inspector, has in practice drawn up presumptive emission limits — specified as milligrams of pollutant per cubic metre of air emitted — but these are used to indicate only whether an operator is making a reasonable effort and have no force in law. Dr Reed's defence of the system is that presumptive limits can be changed rapidly as technological advances allow and that the actual emissions allowed may be altered to suit local circumstances.

Britain has already objected at Brussels to the section of a proposed framework directive on air pollution control that calls for the introduction of Community-wide emission limits agreed by a two-thirds majority. The European Communities' Council of Ministers will meet in March to try and find a way round the impasse. A second proposed directive on fixed emission limits for major combustion plant, which also specifies targets for swingeing cuts in total national emissions, is likely to be opposed by Britain. This proposal is being pushed hard by West Germany which fears that transboundary pollution is contributing to mounting damage to its forests.

But Dr Reed fears that adopting these directives will introduce another tier of authority in Britain for the sake of "one or two European countries which have inadequate controls of their own". Dr Reed also has doubts about a third European directive on air quality standards for nitrogen dioxide. While accepting the principle, Britain should, he says, resist demands for standards that would require costly measures by industry to ensure compliance but which are based on inadequate evidence of need.

Acid rain was the subject of a major speech recently by Mr Ian MacGregor, chairman of the National Coal Board, who said that "after we have crippled some of our basic industries we could then find we had not solved the problem". He pointed out that volcanic activity may emit huge quantities of sulphuric acid into the atmosphere and that some of the reported damage to conifers was unlikely to be due to sulphur dioxide pollution because the trees bore healthy growths of lichen. He concluded that short-term action, such as liming affected waters, should be applied vigorously until science is able to establish the facts. **Tim Beardsley**

Wolf winners

Rehovot

THE winners of the 1983–84 Wolf Foundation Prizes in the sciences have been announced in Herzliya, Israel. The Wolf Foundation was set up in 1976 with an endowment fund of $10 million and the prizes, worth $100,000 each, have become known unofficially as the Israeli Nobel prizes. The prizes are awarded for chemistry, physics, mathematics, agriculture, medicine and the arts, but this year there will be no prize for medicine. (The winner of the arts (architecture) prize has yet to be announced.)

The chemistry prize is shared by three US university professors, Herbert S. Gutowsky of the University of Illinois, Herden M. McConnell of Stanford University and John S. Waugh of Massachusetts Institute of Technology, for the "singular contribution" of magnetic resonance spectroscopy to the theory, structure and dynamics of molecules.

The physics prize is shared by Professor Erwin L. Hahn of the University of California at Berkeley, Dr Theodore H.

Sir Peter Hirsch — a share in the physics prize

Maiman of TRW Inc., Los Angeles, and Sir Peter Hirsch, chairman of the United Kingdom Atomic Energy Authority and professor of metallurgy at the University of Oxford. They are honoured for their work in discovering nuclear spin echoes, for the realization of the first operating laser, and for the development of the scanning electron microscope respectively.

The mathematics prize is shared by Professor Shiing S. Chern of the University of California at Berkeley and Professor Paul Erdos of the Mathematics Institute at the Hungarian Academy of Sciences in Budapest. Both are described as "veteran mathematical giants". The agriculture prize goes to Professor Don Kirkham of Iowa State University and Professor Cornelis T. de Wit of the Agricultural University of Wageningen in the Netherlands, both of whom have made "innovative contributions" to the quantitative understanding of soil/water and other environmental interactions influencing crop growth and yield. The awards will be made in Israel in May. Nechemia Meyers

US space station

NASA seeks partners, purpose

Washington

WITH presidential approval for a space station tucked firmly under his belt, James Beggs, administrator of the National Aeronautics and Space Administration (NASA), is about to tour world capitals in search of international partners for the new venture. And because NASA has still only the sketchiest notion of what it wants from a space station, countries willing to make an early investment can expect a big say in the final design.

During the past two years, while NASA has been arguing the case for a space station, tentative discussions have taken place with the European Space Agency, a number of individual European nations, Canada and Japan. But until last week, when President Reagan gave the space station formal approval in his state of the union message, NASA had been unable to negotiate in earnest.

Beggs is now in an unusually strong position. His status during his overseas tour will be as President Reagan's personal emissary. Meanwhile, one of the principal impediments to foreign collaboration — the involvement of the Pentagon — has been removed. The Department of Defense has so far refused to find a military argument for supporting the new venture. As a result, the space station is being justified by the administration solely on scientific and commercial grounds, and there will be no Pentagon contribution to the $8,000 million development budget.

For overseas partners, however, the most attractive feature of NASA's space station is that it has not yet been designed. Beggs intends to wait for at least another two years before completing plans for the station and beginning hardware development. After the state of the union message last week, NASA was careful to keep the technical specifications of the space station as vague as possible.

All that NASA is saying for the moment is that the station will provide for a permanently manned base in a low inclination orbit. In addition to living quarters for a crew of six to eight, the station will house data-processing facilities and a docking hub for the shuttle. Pressurized modules for scientists and astronauts will be attached to the station, as well as unpressurized free-flying platforms capable of performing a variety of functions.

The purpose of the space station is, so far, almost as vague as its design. Possible roles listed by NASA range from the relatively mundane, such as the tending and repair of satellites and space telescopes, to the frankly exotic. In the long run, NASA maintains, the space station could become the first step towards the establishment of a manned lunar base, or a manned mission to Mars.

Despite its glee at having at last won its battle for a space station, NASA was careful last week to mollify some of the groups that had opposed it. The space science board of the National Academy of Sciences concluded last year that developing a manned space station could not be justified on scientific grounds alone. NASA is now promising to work closely with the space science community and to do its best to ensure that space science funds are not raided to provide funds for development of the space station.

Peter David

US materials science

Setback for Keyworth

Washington

AFTER a year of trouble for his plan to establish a National Center for Advanced Materials (NCAM) at Lawrence Berkeley Laboratory (see *Nature* **301**, 456; 1982), presidential science adviser George Keyworth has bowed to the inevitable and asked the National Academy of Sciences to study priorities for "major facilities" for materials science.

The original NCAM plan met with harsh criticism from many materials scientists who complained that the proposal had been sprung on them without warning and without the benefit of peer review. Responding to these criticisms (and perhaps sensing a budget item that could be raided for several pork-barrel projects), Congress last spring cut the $26 million that the President had proposed for NCAM in his budget for fiscal year 1984 to a mere $3 million and ordered that no more should be spent until a scientific review of the project was completed.

A Department of Energy panel headed by Albert Narath of Sandia National Laboratories was appointed to carry out this review; last fall it declared that the centrepiece of the NCAM proposal, a new advanced synchrotron light source intended as a national facility should not be locked up in a laboratory dedicated to materials research. NCAM has since become mere CAM, and Keyworth's efforts to turn the spotlight on materials science have been pushed back to square one.

The National Academy panel, headed by Frederick Seitz, president of Rockefeller University, New York until 1978, will be considering facilities with an initial cost of $5–10 million or more, including synchrotron and neutron sources. The panel will report next summer, in time for its recommendations to be considered for inclusion in the then President's budget for the fiscal year 1985–86. **Stephen Budiansky**

Bad manners, USA

SIR — I recently had the pleasure of participating at the XVth International Congress of Genetics in New Delhi. I would like to congratulate my Indian colleagues for their successful effort. The congress was well organized, the atmosphere was friendly and congenial and the subjects covered were interesting and diverse. It was one of the best international congresses in the past few years.

However, I feel bound to apologize to the Indian organizers for the rude, inexcusable and unacceptable behaviour of a number of my American colleagues who never appeared at plenary sessions or symposia (as chairmen or as speakers). Their names were called without answer. Obviously their commitment to a "developing" country's meeting was not binding. Furthermore, quite a few failed to send a summary of the paper they were presenting at a symposium. Maybe they do not know that Indian students and young scientists are more eager to read than their counterparts in the United States.

Israel squeezed out

SIR — Israeli scientists will not be able to participate in the 7th International Biotechnology Symposium to be held in New Delhi, India, 19–24 February 1984.

According to the organizers, scientists from countries without an Indian Mission will obtain entry permits/visas if the organizers are contacted at least six months before the symposium. Since July 1983, I have been trying to obtain information on how to apply for a visa, but to no avail. This symposium is sponsored by international organizations such as the International Committee on Economic and Applied Microbiology and the International Union of Pure and Applied Chemistry and should therefore be open to scientists from all countries of the world.

I call upon fellow scientists to boycott this meeting to show their solidarity and to protest to the organizers and the Indian Government that scientists from all countries cannot participate in the New Delhi meeting. The Indian Government's attitude should also be kept in mind when selecting sites for future international meetings.

Creationist view

SIR — Professor Marsden overlooks some important points and makes some logical errors in his recent commentary on the history and sociology of the creation/evolution debate[1]. In his search for a hidden agenda in creationism, he overlooks the legitimate scientific case for creation, and he does not deal with possible philosophical, political, and economic motivations of the other group which seeks to polarize the debate — the evolutionary humanists[2].

He complains about the polarization of the issue as if a middle ground of progressive creationism, based on directed macro-evolution and an old Earth, is supported by scientific data. Professor Marsden has misunderstood radiometric dating and the geological time scale as simple scientific facts (SSFs), just like Newton's third law or the fact that a granite contains potash, feldspar and quartz.

If there were SSFs which indicated that the Earth is old and precluded *fiat* creation, then his point would be well taken. But the methods of evolutionary/uniformitarian geochronology, historical geology and palaeoenvironmental analysis are not SSFs, but rather complex scientific models (CSMs) involving many assumptions, some of which are demonstrably wrong, such as pleochroic haloes in granitic rocks, which are held to prove the constancy of radioactive decay rates through Earth history. Some of these data which argue against the doctrine of uniformity have even been published in *Nature*[3]. The historical assertions that the Cambrian began about 600 million years ago and that the Scopes trial began in 1925 are not equivalent concepts and, as such, should not be taught in the same breath to unwitting students.

Professor Marsden is also wrong in his thesis that we creationists are only a product of some "Post-Civil War cultural crisis". Creationists are convinced by coercive scientific data[4], not solely by conservative theology, demography or profession.

As a fundamentalist, southerner and geologist, I resent several accusations made by Marsden and the implication that a conservative exegesis of *Genesis 9* can support slavery, and that this is part of southern creationists' motivation. I also question his assertion that many southern anti-evolutionists are made because of "the relatively low levels of education of many Southern Bible-believers". I am a creationist because the basic facts of geology (and the other sciences) are consistent with *fiat* creation and several thousand years of Earth history dominated, during brief periods, by processes of catastrophic rate, on a continental scale and of high intensity[5].

Page charge problem

SIR — In scientific publishing a symbiotic equilibrium had been established in which referees evaluate, without payment, papers submitted for publication, in the knowledge that refereeing and publication of papers they themselves submit will be carried out without cost to them. Unfortunately, this equilibrium has been disturbed by a considerable number of (I think exclusively) US journals which now require the prospective author to pay for publication. Many people are therefore being asked to contribute to the publication of journals both by giving free service as referees and also by paying "page charges".

I understand that provision is made on many US research grants for the cost of publication. This is not so in Europe, and it is a practice which, in effect, discriminates against non-US scientists wishing to publish in US journals. Whilst the practice eases the problem for US scientists, the principle of working for, and paying to publish in, the journal seems wrong.

None of us expects or wants payment for refereeing manuscripts. The situation as it existed for many years (and still exists in Europe) was a mutual-help system to which we contributed and from which we benefited. But many scientists and their financiers are unhappy at the extra financial load imposed by some journals.

As a partial solution I propose that referees should ask for page-charge credits which could, wholly or in part, be used to offset the cost of their next publication. In this way no money would change hands and work done by the reviewer would simply result in the amelioration of an added financial burden upon research institutions. The best arrangement, of course, would be to return to the original equilibrium where we paid, and were paid, nothing.

New twist for anthropic principle

The originator of the doctrine that our observations of the Universe are biased because they are made by us now concludes that there have been at most two critical steps in biological evolution.

THE anthropic principle is Dr Brandon Carter's choice of a philosophical middle ground between what he calls the "primitive anthropocentrism" of the pre-Copernicans and "its equally unjustifiable antithesis" of extreme representations of the relativistic cosmological principle, the assertion that, "apart from local inhomogeneities", no place (or time) in the Universe can be privileged in any way. When Carter introduced his principle a decade ago (*IAU Symp.* **63**, 291; 1974), his objective was modestly to point out that the mere fact that our observations of the Universe are made by people who are the products of some 3,000 million years of biological evolution implies an inescapable bias. Carter's latest version of the argument, now published as part of the report of last year's meeting at the Royal Society on the constants of physics (*Phil. Trans. R. Soc.* A **310**, 347-363; 1983) is more radical, and a challenge to biologists as well as astronomers.

The reasons why the anthropic principle should figure in a symposium on the constants of physics are not as surprising as they may seem. The luminosity of a star of given mass, and thus the speed of its evolution from a young star to, say, a red giant, depends linearly on the value of the gravitational constant. If this value were only a little greater than it is now thought to be, the Sun would have run through its evolution faster, so that biological evolution might have got no further than, say, the dinosaurs before the Earth was engulfed by a red giant. And a smaller gravitational constant might never have allowed for the particular circumstances that led to the emergence of living things in the first place. So there is a chance of learning something about the value of the gravitational constant simply by exploiting the circumstance that its evaluation depends on observations made by people. Carter now says that if he had known that the name "anthropic principle" would be so widely used, he would have looked harder for a different way of referring to the bias caused by self-selection.

In passing, Carter directs well-aimed darts at two fashionable preoccupations, speculation about extraterrestrial life and Dirac's large-numbers hypothesis, each of which he says is sustained by neglect of the anthropic principle. Telescoped, the argument is this. The search for extraterrestrial life is based on the hypothesis that the emergence of living things is likely whenever geophysical circumstances are favourable, and thus on a denial of the contradictory hypothesis that the emergence of life is improbable. But, says Carter, the only evidence bearing on the question is the observation (by ourselves) that life has indeed emerged on the surface of the Earth, whence there is no way of distinguishing between the two hypotheses.

Dirac's large-numbers hypothesis is logically identical. Dirac at the outset argued that coincidence between the age of the Universe (strictly, the Hubble time) and the gravitational constant is so remarkable that one must expect the gravitational constant to decrease with time so as to preserve the coincidence. (Numerically, the Hubble time is 10^{58} in units in which the velocity of light, Planck's constant and the gravitational coupling strength are determined by the three-halves power of the square of the proton mass, of the order of 10^{38} in the same units.) Carter's view is that the coincidence is not a coincidence at all, but a consequence of the selection bias occasioned because the observations are necessarily made by people whose existence requires a Hubble time large enough so that some stars can have completed their evolution and have generated the chemical elements of which people are made, but not so long that all stars have run their course.

This is the stuff of lunch-room arguments about the anthropic principle in the past decade. Carter's new departure begins with another coincidence — that between the time-span of biological evolution on the surface of the Earth (say, 0.4×10^{10} years) and the length of time the Sun is likely to spend as a hydrogen-burning star (say 10^{10} years) before becoming a red giant with dimensions engulfing the Earth's orbit.

What connection can there be between two such apparently independent quantities as the timescale of biological evolution, presumably determined by the complexity of living organisms, and the timescale of stellar evolution, determined (in Carter's words) by "the weakness of gravitation"? None, he says. The apparent coincidence is merely a consequence of the "habitual mistake" of overlooking the anthropic principle.

The most plausible way of accounting for it is to suppose that the timescale of biological evolution, itself a Markovian process (one thing leading to another) whose course must be uncertain, is on the average much longer than the time allowed by the lifespan of the Sun as a hydrogen-burning star. So the observation, after a mere 4,000 million years, that there are sentient beings able to contemplate their own emergence is a sign that, in the event, the course of evolution on the Earth has been exceptionally short.

Carter takes this argument one argumentative step further. Suppose, he says, that the evolution of sentient beings depends on n critical steps (defined as unlikely evolutionary steps, which are thus "slow", compared with the majority of evolutionary steps). Then it is possible to show that the chance of all these n steps being completed by time t is proportional to t^n and also to show that evolution (the Sun's time as a hydrogen-burning star or T_0) exceeds that occupied by evolution so far by a quantity of the order of $(1/n)t$. But this time is itself of the order of T_0, whence Carter concludes that n must be a whole number greater than zero and less than or equal to two — in short, either 1 or 2. Carter insists that the general character of this result does not depend on the details of the calculation but acknowledges that it poses a dilemma: how can the fossil record be squared with the conclusion that there have been at most two critical steps in evolution so far? His own preference is to face the dilemma head on; he recommends the evolution of the genetic code and the organization of the nervous system as candidates for the two critical steps.

What weight should be given to this conclusion? In his paper, Carter does not seek to mollify his critics, dismissing the attention being paid to the "inflationary universe" in all its varieties as an attempt to resurrect the "beguiling notion" of the perfect cosmological principle, and complaining that those who hold that only falsifiable hypotheses are admissible are in effect saying that science has accomplished nothing so far.

The Popper school will be further offended that Carter not merely uses the verb "to induce" but that he openly uses the language of Bayesian probability, the calculus of informed guesswork as some consider it. Even his friends may say that he has too lightly discarded the possibility that his coincidence may be explained if evolution is a rapid process which happens on the Earth to have been slow. But Carter is plainly not afraid to stir up trouble and has also provided a tangible example of how the anthropic principle may be made quantitative.

Ecology

A test of ideas about mutualism

from Robert M. May

THE past few years have seen some sharp debate over the extent to which competitive interactions are of importance in determining the structure of plant and animal communities[1,2]. In this debate, it is sometimes claimed that the 1960s and 1970s were an era in which researchers regarded competition as essentially the only force moulding community structure. Such charges are clearly exaggerations, as these two decades equally saw an upsurge in empirical and theoretical work on predator–prey and parasitoid–host interactions. Any contemporary ecology text, American or British, reflects this attention given both to competitive and to predator–prey associations. What is true, however, is that mutualism has remained relatively neglected — in field, laboratory, theory and textbooks — until recently.

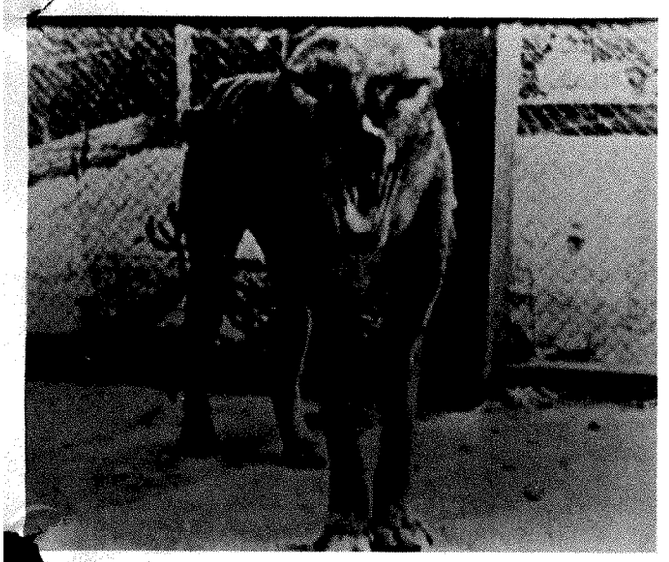
Why this relative lack of attention to mutualism? My view is that it is partly because tight mutualistic associations between clearly distinct species (as opposed, for example, to entities like lichens, where algae and fungi have fused into something akin to a single organism) are less conspicuous in temperate regions than are competitive or predator–prey associations; only relatively recently has there been much ecological research in the tropics where mutualistic interactions are conspicuous elements of community organization. The idea that obligate mutualisms may be dynamically fragile (and consequently more likely to be found in the environmentally stable tropics) essentially goes back to Darwin and Wallace, who both noted that obligate associations between plants and pollinators are not easily transported to islands. These ideas are explored in more detail elsewhere[3,4].

D.S. Wilson has advanced an interesting alternative explanation for this relative neglect of mutualism[5]. He argues that the controversies about group selection in the 1960s led to a sharper recognition — crystallized in Williams's important book[6] on *Adaptation and Natural Selection* (1966) — that conventional Darwinian selection acts on individual organisms, not on groups or species as such. Much of the earlier discussion of mutualism, however, made implicit or explicit appeal to adaptations that benefited groups rather than individuals. Wilson notes that many older textbooks, such as the influential *Principles of Animal Ecology* (1949) by Allee *et al.*[7], had treated mutualism as a dominant interaction in well-ordered communities; but the explanation was in terms of the adaptation of species rather than individuals. Williams argued that mutualism can evolve, but only if conditions are such that it is advantageous for the individual involved, and he went on to observe[6] (p.247) "really good examples of mutualism are relatively rare, and it must be that these necessary [conditions] seldom arise".

Contemporary theory, as developed by Wilson[8,9] and Wade[10] (and reviewed by Uyenoyama and Feldman[11] and others[12]), considers more explicitly the effects that group size may have on the evolution of mutualistic associations. Suppose a species contains both mutualistic and nonmutualistic types: the mutualist benefits another species in its vicinity, but at a cost, c, to itself; the enhanced presence of the other species reciprocally confers a benefit, b, on all N individuals (mutualists and nonmutualists alike) in the group of which the mutualist is a member. It is clear that the proportion of mutualists must decrease in any group containing both types, because they alone bear a cost while the entire group benefits: this constitutes an evolutionary force against mutualism. But groups with many mutualists will, by virtue of the benefits conferred, produce more offspring than those with few mutualists: this constitutes an evolutionary force favouring mutualism. Thus these models suggest that[5] "the evolution of mutualism is a balance between the opposing forces of relative fitness within groups (individual selection) and the differential productivity of groups (group selection)"; The outcome will depend on the costs c, benefits b and — most important — on the degree of variability in group sizes (which variability will, under most statistical assumptions, be more pronounced if the average group size N is relatively small): mutualism will be favoured by small c, large b and small N.

Unfortunately, experimental tests of these ideas are difficult. For one thing, the parameters c and b can be hard to define, much less measure, in field settings. For another, the effective group size N may be smaller than it appears, either because apparently large groups actually derive from a small number of colonists, or because the population structure results in very large variation in size among groups (promoting the evolution of mutualism).

Wilson has fastened on the association between burying beetles and the mites they carry around as a system that may be particularly amenable to field and laboratory exploration of these questions about mutualism[5]. The associations he has been studying include five sympatric species of burying beetles of the genus *Nicrophorus*. These creatures are carrion feeders. They raise their broods on small carcasses (mainly dead rodents); the carcass is first buried, and the beetles then remove its hair and roll it into a ball. This remarkable sequence of actions is carried out by a pair of beetles, after which the male leaves while the female remains until her brood has completed its larval development. In northern Michigan, carried around on these beetles are some 15 species of mites from four families and at least one species of nematode. These 'phoretic' mites disperse to new habitats by attaching to the beetles and then abandoning their carriers at the new habitat to follow a free-living existence; the larval mites develop on buried carcasses, side by side with the beetle larvae that represent the mites' next 'aeroplane'. When mites leave their beetle host to take up residence on a buried carcass, they search out and destroy (by piercing with their chelicerae) fly eggs that may be present; thus the mites may benefit the beetles by reducing competition for carcasses by flies. Finally, Wilson observes that mixing of adult mite populations takes place at large unburiable carcasses where large numbers of beetles congregate to feed.



In short, these associations between phoretic mites and burying beetles exhibit the conjunction of characteristics envisioned in the models described above: on the one hand, local 'trait groups' of different sizes, in which mutualistic effects may be present, are found on individual buried carcasses; on the other hand, there is mixing of groups at the large carcasses where adult beetles feed communally.

Wilson focuses mainly on field and laboratory studies of the association between the mite *Poecilochirus necrophori* and the beetle *N. tomentosus*. He shows that such beetles carry on average about 12 *P. necrophori*, which (given that carcasses are buried by a male and female pair of beetles) makes the average group size rather large, $N \sim 24$; Wilson also shows there is much variability in the size of these groups. A complicated series of experiments can be summarized as broadly leading to the conclusion that the mites' habit of piercing the eggs of flies strongly enhances the breeding success of the carrier beetle species: in field studies, *N. tomentosus* raised broods of average weight 0.092 g from 26 of 30 buried carcasses when *P. necrophori* was present, while broods of average weight 0.088 g were raised from 15 of 28 buried carcasses in the absence of *P. necrophori*; this overall twofold difference in reproductive success is statistically highly significant.

Wilson discusses the possibility that the mites may pierce eggs purely to feed on them, so that the beneficial effects to the beetles are incidental rather than the outcome of a co-evolved mutualism. Were this the case, it would be expected that mite fecundity would be correlated, to some extent, with the presence of fly eggs. But a variety of laboratory and field experiments shows no correlation between mite fecundity and abundance of fly eggs; even the total absence of eggs has no discernible effect, as the mites reproduce well on the carcass itself. Costs associated with the egg-piercing behaviour are harder to document

Last gape of the Tasmanian tiger

THAT most curious of marsupials, the thylacine or 'Tasmanian tiger', is commonly assumed by zoologists to be extinct. The last known specimen died in captivity in Beaumaris Zoo, Hobart on 7 September 1936 after a deadly campaign led by Tasmanian sheep-farmers over the preceding half-century. Anecdotal reports of more recent encounters notwithstanding, no solid evidence has been forthcoming since then despite several major expeditions and many forays by wildlife enthusiasts.

Thylacinus cynocephalus — literally 'pouched dog with a wolf head' — managed to combine a lupine visage with a tiger's stripes, a snake's gape, a kangaroo's tail and a unique rear-opening pouch (the thylacine loped about on all fours and would otherwise have risked injury to its young from rough undergrowth). From nose to tip of tapering tail the thylacine measured up to 2 metres, in height 55 cm and in weight 20 kg, thus qualifying as the largest carnivorous marsupial. Although its tawny fur and other external characteristics can be seen in pelts preserved at the British Museum (Natural History) and elsewhere, the astonishing capacity to open its jaws to an angle of over 120° is best appreciated on this unique surviving photograph, the last recorded gape of the Hobart specimen *circa* 1935. The two frames are reproduced from an 8-mm film by courtesy of the State Library of Tasmania.

The latest in a long line of claimed sightings was made in 1982 in northwestern Tasmania by a ranger of the National Parks and Wildlife Service, according to just released press reports. The news had been kept secret to deter hunters and sightseers, but the deployment of trip cameras and sand traps over the last eighteen months yielded neither photographs nor spoor. □

This is the first in a series of historic scientific photographs which will be appearing in News and Views. *They are selected from* Beyond Vision *by Jon Darius, to be published in April by Oxford University Press.*

(and if there are no costs, then in the above models mutualism can of course evolve in groups of arbitrary size). Wilson suggests two kinds of cost, which he hopes to quantify in future experiments. First, since the mites' diligence in piercing every egg they can find apparently pays no dividend in enhancing reproductive success, it represents a departure from optimal foraging; this is likely to carry some cost, even in the mites' food-rich environment. Second, the habit of *P. necrophori* of leaving its beetle carrier upon discovery of a carcass incurs the substantial risk of the carcass being appropriated by some other species of animal. As Wilson observes[5], "A mite that abandons its carrier only to have it fly away has made a poor choice, and I do occasionally observe a few *P. necrophori* wandering forlornly around a half-built burial chamber that has been robbed by a mammal. Yet the carrier must be abandoned to pierce fly eggs. Assuming that the beetle does not force abandonment, this may represent the greatest potential cost of the mutualistic behavior".

As Wilson emphasizes[5], this research programme is still in its formative stages. The existing work does a lot towards quantifying the benefits and the population structure of one particular mite–beetle association, but there is a need for more information (particularly about the costs). Beyond this, it can more generally be remarked that burying beetles live in a very competitive environment, where their relatively slowly developing larvae (the eggs hatch several days after the carcass is buried, and larvae take 10 to 20 days to complete their development) must contend both with faster developing flies (where the span from egg to adult fly takes seven days or less) and with the problem of 'spoilage' of the carcass by microbial activities. The mite *P. necrophori* is just one member of a diverse phoretic community; *N. orbicollis* species in northern Michigan, for example, typically carry seven species of mites and at least one nematode species. Wilson suggests that, as most of the mites filter microorganisms, these mite–beetle associations may represent elaborately co-evolved mutualisms (with prevention of spoilage of the buried carcass being an important component), in spite of average group sizes exceeding 100 mites per beetle. He concludes that[5] "it seems possible that the beetles and their phoretic associates have congealed into a multispecies mutualistic network that systematically alters the local environment in ways that cause its own perpetuation. If so, then the structure of these miniature communities more closely resembles the view of Allee *et al.*[7] than more modern ecological theories". In its larger aspects, Wilson's experimental study will of necessity unfold slowly. □

Gene expression

The end of the message and beyond

from Nick Proudfoot

SINCE last reviewed in these columns a little over a year ago[1], several major steps forward have been made in understanding how the 3′ ends of eukaryotic mRNA are formed. First and foremost, histone genes have joined other eukaryotic RNA polymerase II genes in generating their 3′ ends not by simple termination of transcription, but by termination followed by post-transcriptional cleavage. The activity responsible for this process has been nearly purified and looks very much like a small nuclear riboprotein or 'snurp', not the U1 snurp responsible for intron splicing, but another as yet unidentified one. Second, mutation of the AAUAAA conserved sequence found at the 3′ ends of poly(A) containing mRNAs has been shown to cause elongation of the mRNA transcript[2]. This formally proves that the AAUAAA sequence is required for mRNA 3′ end formation, and strongly suggests that the sequence is a signal for endonucleolitic cleavage. Finally, the feeling that RNA polymerase II must have a precise termination process, rather than just falling off the gene template at random, has been virtually proven, at least for the mouse β major globin gene.

Max Birnstiel's laboratory in Zurich has been working on the transcription of sea urchin histone genes by injecting them, together or separately, into *Xenopus* oocytes[3,4]. Not surprisingly, several of the activities necessary for the generation of sea urchin histone mRNA are absent in oocytes. Birnstiel's group therefore tried co-injecting sea urchin extracts along with the histone genes to complement the oocyte transcriptional apparatus[5] and found that with the extracts, histone gene H3 does generate mRNA that terminates at the correct 3′ position, while without the extracts it does not. Purification of the activity using this complementation factor assay[6] has now revealed that it is a nuclear RNA–protein complex known affectionately as a 'snurp'. Indeed, even a 60-nucleotide RNA fraction free of protein stimulates the production of correct histone mRNA 3′ends when injected along with the histone gene into oocytes — presumably oocytes can package the RNA into a snurp[7]. Although this group's experiments strongly imply that histone mRNA 3′ ends are generated by endonucleolitic cleavage, the final proof has come from other work.

Krieg and Melton of Harvard University[8] took a different histone gene, placed it under the influence of a bacteriophage (SP6) promoter[9], and synthesized *in vitro* transcripts extending beyond the 3′ end of the mRNA. When these RNAs were injected into oocytes, correct histone mRNA 3′ ends were created, proving that a precise RNA endonuclease activity is present in oocytes, capable of producing histone mRNA 3′ ends. Similar results have been obtained by Birnstiel's group (unpublished data) and by Carl Parker at Caltech (personal communication). Presumably the 'histone snurp', either single-handed or with the help of other activities, cleaves the histone mRNA primary transcript at the mRNA 3′ end position.

Birnstiel's group has now gone on to define rather precisely what these activities recognize in the primary RNA transcript[10]. Clearly, the hairpin at the histone mRNA 3′ end is all-important, although site-directed mutagenesis shows it does not matter exactly what sequence the hairpin has, as long as base-pairing is maximized. Also, the immediate 3′ flanking sequence to the hairpin structure appears to be necessary to form the mRNA 3′ end. In other words, the recognition site for cleavage is fairly complex — and that will make the precise biochemistry of the RNA–protein interactions hard to unravel.

Understanding of the processes involved in the formation of poly(A)-containing mRNA 3′ ends has similarly progressed. The conserved sequence AAUAAA is clearly important as two site-directed mutagenesis experiments show. In one case[11], the adenovirus E1A poly(A) site was mutated to AAGAAA, causing all E1A transcripts to extend into the next E1B gene as cleavage at the E1A mRNA 3′ end was prevented. In the second case[12], experiments on a new type of non-deletion α-thalassaemia discovered in Saudi Arabia (Saudi α-thal) have shown that the human α2 gene contains a single base change in the poly(A) site, AAUAAG, that again results in the production of α-globin mRNA with 3′ ends extending way beyond the normal 3′ end. These transcripts are unstable in human reticulocytes so insufficient globin is produced and the α-thalassaemia phenotype is seen.

Clearly, these two studies strongly suggest that AAUAAA forms part of a recognition signal for the endonucleolitic cleavage necessary to generate a correct mRNA 3′ end. A recent theoretical study by Susan Berget[13] neatly lends support to this presumption. She argues that the AAUAAA sequence, together with another less convincing sequence homology CApyUG, usually found close to the site of poly(A) addition[14], can base-pair reasonably well to a small nuclear RNA called U4. She assumes, of course, that cleavage at the AAUAAA sequence is yet another snurp-mediated process.

Considerable progress has also been made in understanding the first snurp to be talked about, U1. Since the original sequence homology arguments[15,16] that suggested U1 could base-pair with intron donor and acceptor sites[17,18] and thereby facilitate intron splicing, several more direct experiments have been carried out. Work in Joan Steitz's laboratory, where the term 'snurp' was first coined[19], has demonstrated the direct interaction of U1 with an intron donor site[20]. Also, very recently, *in vitro* splicing of adenovirus introns has been convincingly demonstrated in HeLa cell extracts[21,22]. Using this *in vitro* splicing system, Phillip Sharp's laboratory, in collaboration with Joan Steitz, has demonstrated the inhibition of *in vitro* splicing by antibodies directed against U1 snurps[23]. Further evidence comes from Hernandez and Keller[22] who have partially purified one 'splicing' component of the *in vitro* splicing extract and shown that this fraction co-purifies with snurps.

Finally, yeast introns have been shown to contain their own U1-like sequence actually as part of the intron sequence close to the 3′ acceptor site[24,25]. If it performs the right contortions the sequence may be able to interact with the donor site and mediate intron excision. It would thus seem that there is one general mechanism for the post-transcriptional processing of RNA polymerase II gene transcripts: each cleavage event, be it the removal of an intron or the formation of a mRNA 3′ end, is initiated by specific sequence recognition between the gene transcript and a small nuclear RNA. Activities associated with this RNA (that is, the snurp proteins) then cleave the gene transcript and are followed by RNA ligation in the case of intron removal, or by polyadenylation in the case of mRNA 3′ end formation.

Returning to the 3′ end of the mRNA, if, as described above, both histone and poly-(A)-containing mRNAs generate their 3′ ends by RNA cleavage, then where does RNA transcription actually stop? Specific RNA termination sites have been demonstrated in bacteria, so we might expect eukaryotes to have them too — and indeed this has now been shown to be the case, at least for the mouse β major globin gene. Jim Darnell and his colleagues at the Rockefeller University, New York, have precisely pinpointed a position about 1 kilobase beyond the end of the gene, beyond which no RNA transcripts can be detected[26,27]. They used a tissue culture cell line — the mouse erythroleukaemic Friend cell — that can be induced by various chemicals such as dimethyl sulphoxide to express high levels of globin mRNA and protein. By pulse-labelling the cells with [α-^{32}P]UTP, newly synthesized precursor RNAs were ^{32}P-labelled. Nuclear RNA was then purified and hybridized to single-strand 3′ flanking region DNA fragments

0028-0836/84/050412-01$01.00

cloned into the single-strand bacteriophage vector M13. The RNA–DNA hybrids obtained were next treated with ribonuclease and the protected RNAs fractionated on gels. One 3′ flanking region M13 clone protected RNA for only half of its length. The 3′ flanking region M13 clones taken from in front of this clone protected RNAs for their whole length, whilst the 3′ flanking region M13 clones from beyond the clone produced no protected RNA. These results clearly show the presence of a discrete RNA 3′ end well beyond the end of the mRNA. It seems likely that Darnell's experiments have identified a eukaryotic termination site. If such a site exists in the mouse β major gene, then it seems plausible that many, if not all, eukaryotic genes have termination sites.

Why are the termination of transcription and the formation of mRNA 3′ ends separate processes? Well, what at first sight appears an unnecessary complexity may perhaps give an additional control over gene transcription. We may find that specific factors modulate the efficiency of trancriptional termination. If termination were prevented, then either the primary transcript could be rendered even more unstable, so that less mature mRNA could be produced from it before it turned over, or alternatively, transcription might read through into the next gene and disrupt its normal transcription. Obviously, these possibilities are only speculation. But the view that all the controls that modulate eukaryotic gene expression centre on the promoter may well prove too narrow. □

Developmental biology

Morphogenesis by fibroblast traction

from Julian Lewis

THE fibroblasts that make up the extracellular matrix in the adult body may seem dull, commonplace cells, cast in a supporting role while others play the star parts. But fibroblasts in the embryo appear in a more interesting light. They are the cells that carry much of the information that dictates the structure of the skeleton[1], the locations of the muscles[2], the routes of the nerves[3] and the patterning of the skin[4]. They are the architects of connective tissue as well as the makers of the raw materials. They work on the collagen that they have synthesized and secreted, compacting it into sheets, drawing it out into cables, crawling over it, tugging upon it; and with its help, controlling the disposition of other cells and organs[5].

Though fragments of evidence have been available for a long time[6], it is only recently that experiments have brought the mechanical role of embryonic fibroblasts clearly into focus. A fibroblast alone in a culture dish will crawl about: it extends its leading edge, adheres with it to the substratum and uses the new site of anchorage to pull itself forwards, probably by an actin-based contractile mechanism. In the process, the fibroblast elongates itself for its trailing edge also is stuck to the substratum and does not easily detach.

Since action and reaction are equal and opposite, a force must be exerted on the substratum, tending to put it into compression in the region between the two ends of the fibroblast and into tension beyond them. The force can be made visible by culturing the cell on a very thin sheet of silicone rubber, which is thrown into compression wrinkles beneath the cell and into tension wrinkles beyond its ends[7]. The compression wrinkles run transverse to the long axis of the cell, while the tension wrinkles radiate from its ends.

Fibroblasts show their strength in a more dramatic way when they have collagen fibres to work on, instead of a rubber sheet. The clearest demonstration has come from experiments using an artificial collagen gel prepared from a solution of dissociated collagen subunits which is poured into a Petri dish and allowed to set by reassociation, forming a mesh of randomly oriented collagen fibrils. Living fibroblasts can be added so as to create a sort of artificial loose connective tissue in which the cells are uniformly dispersed. The gel then contracts away from the walls of the Petri dish, squeezing fluid out of the meshes of the collagen, and by the end of the week is compacted into a pellet with a diameter which may be less than a fifth of the original — corresponding to a volume less than a hundredth of the original[5-8]. The contraction occurs only if fibroblasts are present, and it can be prevented by adding cytochalasin, which is known to disrupt actin filaments and hence the intracellular contractile mechanisms that depend on them[8]. If vertical pegs are fixed to the base of the dish to prevent contraction of the gel, then collagen is stretched into rope-like bands that loop around the peg and are pulled so taut that they will often snap[5].

The contraction of the artificial gel is clearly similar to the contraction of granulation tissue in wound healing, well known to pathologists, who have coined the term 'myofibroblast' to describe the muscle-like nature of the fibroblasts that bring it about[9]. In fact, studies of wound contraction provided the earliest clear evidence of the force-generating role of fibroblasts in a collagen matrix[6].

There is, however, a major difference between the action of fibroblasts and that of muscle cells. Muscle cells are permanently attached at both ends to other structures, and bring about contraction of the tissue simply by shortening themselves. The fibroblast does more: while exerting a contractile force, it changes its points of attachment, hauling in more and more collagen, as a sailor hauls rope hand-over-hand. Indeed, the analogy goes further. Just as sailors use their ropes to manoeuvre the masts and sails, so fibroblasts use collagen fibres to pull the parts of the developing body into their proper positions; and just as sailors can swarm up the rigging, so fibroblasts can swarm along the collagen fibres that they have themselves formed and aligned.

These points are illustrated by further experiments *in vitro*[5]. If a small chunk of tissue containing fibroblasts is excised from a chick embryo and placed in a collagen gel that is otherwise cell-free, it will begin to draw in collagen from its surroundings, creating for itself a capsule of densely packed and circumferentially oriented fibres, and further out, beyond the most peripheral fibroblasts, setting up stresses that orient the collagen radially. If two such explants are placed far apart in the gel, a very striking 'two-centre effect' is seen: along the line that joins them, in the cell-free region, the collagen becomes organized into a compact band of aligned fibres[10]. Thus if embryonic cartilage rudiments, stripped of loose connective tissue but retaining a thin layer of perichondrial fibroblasts, are placed in the gel, they recruit for themselves thick new coats of perichondrial collagen and become linked by oriented collagen bands resembling

© 1984 Macmillan Journals Ltd

ligaments.

If small chunks of embryonic muscle tissue (consisting of muscle cells mingled with fibroblasts) are also placed in the dish, they become connected to the cartilage rudiments and to one another by bands of collagen equivalent to tendons; the muscle fragments, initially shapeless blobs in random positions, become stretched out into well-formed muscle bellies and are towed into place by the collagenous attachments to the skeleton[5]. Paradoxically, the muscle cells appear to be the passengers rather than the engines of such movements. In an embryonic limb bud that has been deprived of cells capable of developing into muscle, the skeleton at first forms normally, and so do the tendons, even though they have no muscles to pull on them[11].

Oriented fibrils in an extracellular matrix can orient cell movements (as a paper in this issue of *Nature*, p.453, from Norio Nakatsuji and K. Johnson demonstrates in the context of the amphibian gastrula[12]). When fragments of tissue are explanted into a collagen gel, cells — presumably fibroblasts — migrate out into the uninhabited regions of the gel; and the migrants move most rapidly, and in largest numbers, along the dense oriented bands of collagen that have been created by fibroblast traction. Thus the fibroblasts govern the disposition of collagen, and the collagen in turn affects the disposition of the fibroblasts.

Furthermore, a strong and active cluster of fibroblasts surrounded by collagenous matrix will tug towards itself not only the matrix but also any fibroblasts that may be clinging to it. Once recruited into the cluster, these cells will add to its strength. Thus inhomogeneities in the distribution of fibroblasts will tend to be self-amplifying.

Clearly, fibroblasts and collagen fibres together make a most remarkable dynamic system. A recent paper defines its properties in mathematical terms and discusses its capabilities for pattern formation[13]. For example, a homogeneous tissue of fibroblasts dispersed in a random matrix may become unstable against small departures from uniformity, and so spontaneously develop a pattern in which the cells become clustered and the collagen becomes organized into tracts.

Just such a phenomenon is seen in the skin of a bird embryo as feather tracts form. The fibroblasts of the previously almost uniform embryonic dermis gather into a regular lattice of condensations, corresponding to feather rudiments, linked by oriented bands of collagen. The whole transformation is blocked in the presence of collagenase[14]. In appropriate conditions, an artificial gel of collagen containing dispersed fibroblasts will show roughly similar behaviour[15,16]. Theory and experiment here converge in a most persuasive way.

A bolder and more dubious application of the theory of fibroblast traction aims to explain the origins of the pattern of long bones in a developing limb as a result of mechanical instabilities in the mesenchyme of the undifferentiated limb bud, creating non-uniformities where none existed before[13]. Limb-bud specialists are likely to be sceptical: there is too much evidence that cells of the apparently undifferentiated mesenchyme are already intrinsically different and determined for the formation of specific skeletal structures even before any cartilage 'condensations' are visible[1]; and the patterning of the skeleton seems too insensitive to artificial and mechanical disturbances. There is surely more to pattern formation in the developing limb than mechanical instabilities generated by fibroblast traction: but it is no less sure that fibroblast traction plays a major part in the process. □

Obituary

Ahmad Bukhari 1943–1983

from Neville Symonds

AHMAD BUKHARI had exercised a formative influence on research in transposable elements for close to a decade and was at the height of his powers when he died suddenly of a heart attack on 19 November 1983.

His earliest major contribution, in 1975, concerned the excision of transposable elements, an issue he always felt was undervalued in the rush to understand how replicative transposition occurs. He was able to show that most bacteriophage Mu insertions in a host gene could be excised exactly with the restoration of gene activity, so demonstrating for the first time that Mu transposition normally occurs without any damage to target DNA sequences.

With regard to replicative transposition, he and Ljungquist published a crucial paper in 1977 showing that coupled transposition and replication of Mu proceeds without Mu leaving its original prophage site. Using an ingenious combination of restriction analysis and DNA–DNA hybridization, they examined the state of prophage Mu DNA after induction and were able to demonstrate conclusively that the original Mu–host junction fragments remained intact well into the latent period after many rounds of replication had occurred.

Bukhari's strength as a scientist rested on his ability to see problems as a whole and to appreciate the elements that were crucial to their understanding. This is exemplified in the beautiful review he wrote for *Annual Review of Genetics* (**10**, 389) in 1976, 'Bacteriophage Mu as a transposition element', in which he brought together the known experimental findings about Mu, assessed their importance from the viewpoint of transposition, indicated the areas where further ideas and investigations were needed and finally related Mu behaviour to that of other insertion elements.

Recently, research on Mu at Cold Spring Harbor has focused on the mechanism by which Mu transposes, paying particular attention to the findings that transposition sometimes leads to replicon-fusions (alternatively called co-integrates) and sometimes to simple insertions. These studies led Harshey and Bukhari to propose a variant to the Shapiro model for transposition which has stimulated a considerable amount of theoretical discussion and practical activity, and which is supported by observation of Mu transposition intermediates using electron microscopy.

Bukhari was born in the Punjab and was an undergraduate at the University of Karachi, leaving for the US in 1966 to carry out graduate studies at Brown University and the University of Colorado. From 1970 he worked continuously at the Cold Spring Harbor Laboratory, and was the centre of one of the most active research groups working with bacteriophage Mu.

As a person Bukhari was emotional and enthusiastic with a variety of interests and friends. He maintained his connections with Pakistan, at the personal as well as the scientific level, and was a scientific adviser to both UNESCO and UNIDO. He will be sorely missed both for his intuition as a scientist and for his humanity as a friend. □

Molecular biology

Multiple forms of mitochondrial DNA in higher plants

from Thomas D. Fox

THE study of the structure of the mitochondrial genomes of higher plants is a daunting task. Simply in terms of size there are problems enough — the genomes can contain from about 200 kilobases (kb) to over 2,000 kb of primarily unique sequence, according to species. In comparison, human mitochrondrial DNA, which appears to code for roughly the same number of products, is only 16.5 kb long. Worse yet, electron microscopy of plant mitochondrial DNA reveals a complex assortment of differently sized circular and linear molecules, and restriction digests contain fragments in sub-stoichiometric amounts, suggesting a heterogeneous structure (for a review see ref. 1).

Some semblance of order in this situation has now been provided by the restriction mapping studies of Palmer and Shields[2], reported in this issue of *Nature* (see p.437). Their results suggest that plant mitochondrial genomes are carried on discrete circular molecules which are derived from each other by recombination.

Chromosome walks along the mitochondrial DNA of *Brassica campestris* (Chinese cabbage, turnip) led around three differently sized circles. The largest, 218 kb long, contains the entire sequence complexity of the *Brassica* mitochondrial genome. This 'master chromosome' contains a major direct repeat of about 2 kb, whose elements are separated by 135 kb on one side and 83 kb on the other. The other two circles are 135 and 83 kb in size and each contains the corresponding sequences present between the repeats of the master chromosome and a single copy of the repeated element. (Other arrangements, such as dimers of the 218 kb circle, are consistent with the mapping data *per se* but fail to explain the stoichiometries observed for fragments containing the repeats and surrounding unique DNA.) Clearly, a simple way to account for these species is to assume that they are related to each other by homologous recombination between repeated elements.

As Palmer and Shields point out, this relatively simple tripartite picture may turn out upon further study to be complicated by the presence of other minor species. One would, for example, expect the presence of dimers of the 83 kb and 135 kb circles to be present. Furthermore, Palmer and Shields detected, but did not map, other minor repeated sequences in *Brassica* mitochondrial DNA which may also serve as sites for recombination.

Mapping studies on the much larger mitochondrial genome of maize by Lonsdale and co-workers at the Plant Breeding Institute and University of Cambridge (personal communication) have indeed revealed a similar but more complex picture. They have mapped a maize mitochondrial DNA master chromosome of 570 kb and located six pairs of repeated elements within it: five direct repeats and one inverted repeat. In addition, six other smaller circular maps, ranging in size from 47 to 503 kb, were generated and could be derived from the master chromosome by recombination between pairs of repeated elements. These smaller circular maps seem to correspond well in size to circles identified in maize mitochondrial DNA by electron microscopy[3]. Thus the presence of multiple circular species of DNA, related by recombination between repeated elements, may be a general feature of higher-plant mitochondrial genomes.

The study of recombination in plant mitochondrial DNA has been hampered both by the lack of genetic markers and because mitochondrial DNA is maternally inherited. Nevertheless, evidence for recombination has been obtained by somatic cell hybridization of strains differing in polymorphic mitochondrial DNA restriction fragments[4-6]. The hybrids typically contain new combinations of parental fragment types, as might be expected from the assortment of multiple circular DNAs during mitotic growth. In addition, many hybrids contain novel fragments not found in either parent, which most probably arise as a result of true crossing-over. Complete restriction maps of plant mitochondrial DNAs will allow the detailed analysis of recombination in somatic cell hybrids.

Whether plant mitochondria contain a general recombination system, such as that present in yeast mitochondria, is not yet clear. They may contain site-specific recombination systems which only function at some repeated elements — a possibility suggested by the finding of repeated elements in maize mitochondria DNA that are not surrounded by the expected recombinant set of restriction fragments (D.M. Lonsdale, personal communication). Site-specific recombination would tend to limit the number of different circles that could be generated from a master chromosome containing many repeats. (The large number of linear molecules in preparations of mitochondrial DNA from plants, as well as yeast, are assumed by most workers to be the result of *in vitro* degradation. Perhaps some of these linear molecules are recombination intermediates present *in vivo*.)

Progress in identifying plant mitochondrial genes through their homology with genes of other organisms will soon make it possible to see whether the arrangement of genes is conserved, as in animals, or not, as in fungi. Using the restriction maps of the maize genome, D.M. Lonsdale and C.J. Leaver of the University of Edinburgh (personal communication) have already shown that the genes coding for cytochrome oxidase subunit I, apocytochrome *b* and a protein homologous to that encoded by the human unassigned reading frame *URF1* are present in a cluster. The cluster also contains sequences derived from chloroplast DNA containing what appear to be pseudogenes for chloroplast 16S rRNA[7] and the large subunit of ribulose bisphosphate carboxylase[8]. About 200 kb away is another gene, for cytochrome oxidase subunit II[9], and midway between them, the rRNA genes.

Comparisons between species such as *Brassica* and maize will also help give some clues as to why the majority of plant mitochondrial DNA sequences appear not to code for useful products. That chloroplast DNA sequences[7,8] are found in maize mitochondrial DNA led Lonsdale to suggest that the ability to take up foreign DNA could in part account for the large and variable sizes of plant mitochondrial genomes. It will be interesting to see how true this is of other species, and whether *bona fide* nuclear DNA sequences also turn up in plant mitochondria. □

100 years ago

BULLETIN No. 3 of the Entomological Division of the U.S. Department of Agriculture (Washington, 1883), when stripped of the "red-tape" that appears to be even more necessary on official documents in the States than it is in this country, is of more than usual interest. The notorious "army-worm" appears in a new character, viz, as destructive to cranberries, which form an important feature in the production of the States. A long chapter is devoted to the "cotton-worm" in which (in addition to interesting biological information) elaborate contrivances for distributing arsenical solutions are described.

Palaeobathymetry from sinking shells

from Peter J. Smith

THE variety of phenomena from which information can be wrung about the geophysical past is a constant surprise. Consider, for example, the case of the sinking cephalopods.

A few years ago, J.S. Weaver and J.A. Chamberlain, building on earlier ideas and making use of the equations derived by naval architects to describe the sinking of ships, managed to work out the physics of the sinking of coiled and chambered shells (see, for example, *Math. Geol.* **10**, 673; 1978). They were able in particular to demonstrate, both theoretically and by laboratory experiment, that the depth to which an intact coiled cephalopod will sink with its plane of symmetry remaining vertical is governed only by the geometry of the shell. What was not clear at the time was whether, given the more chaotic conditions of the natural environment, observations of *in situ* vertical cephalopod shells could be interpreted sensibly in terms of palaeobathymetry. R.E. Crick has now shown that they can be (*Bull. Geol. Soc. Am.* **94**, 1109; 1983).

This is possible because of the remarkable series of events that overtakes chambered cephalopods after death. Gases released during the decay of the visceral mass often increase the buoyancy of a dead cephalopod so that the shell rises to the water surface where, unless it is stranded on a shoreline, it becomes waterlogged and sinks. But it doesn't just drop. Initially, the shell floats with its plane of symmetry vertical; but as it gradually absorbs water and sinks (and assuming it remains undamaged) it begins to rock from side to side until it finally becomes horizontal. The depths at which these changes occur depend on the shell's geometry. If the water is shallower than the rocking depth for a particular type of cephalopod, the shell will reach the bottom and become anchored, infilled and buried in a vertical position. Therefore, any ancient cephalopod shell discovered in a vertical position must have been deposited in water whose maximum depth can be estimated from the shell's geometry.

Of course, there are potential difficulties. For example, could a sinking shell, having reached the depth at which it becomes horizontal, nevertheless end up in a vertical position through impact at the bottom? That seems unlikely, for cephalopod shells float down much too gently to undergo a disorienting impact.

Second, could shells reaching the bottom in a horizontal state subsequently be turned to the vertical by bioturbation? They could indeed, although there are ways of detecting that in particular cases.

Third, it is necessary to assume (reasonably) that gravity, seawater density and atmospheric pressure have not changed since the shells sank.

Finally, if the method is to work, it is essential that not all shells that end up in a vertical position at the bottom should subsequently topple over; but as vertical shells are actually observed, this appears not to be too much of a problem.

Crick has applied the technique to the top of the Fort Worth limestone, which extends in a narrow belt southwards from the Texas–Oklahoma border and which formed during the extistence of the East Texas Embayment (Lower Cretaceous). There are enough vertical cephalopods (ammonites and nautiloids) to provide data at points throughout the whole length of the formation; and there were several different types of cephalopod present, so that maximum water depths can be determined over the range 1.6–2.6 m. Moreover, at the few points at which there are no vertical shells and hence at which it is not possible to specify maximum water depths, it has at least been possible to estimate minimum depths, for the depths must have exceeded those at which the particular types of cephalopod begin to deviate from vertical sinking.

The conclusions that Crick reaches are that the Forth Worth cephalopods were laid down in water depths of generally less than 2.6 m and that depths increased slightly to the east and south. In the context of local geology, this is a considerable advance in that previous estimates of water depth based on less reliable (sedimentological and palaeoecological) criteria lie in the range 15–40 m. More important than the specific results, however, is that the method appears to work and is evidently of wider applicability. The only condition is that the formation to be studied should contain cephalopods laid down in water of a depth not exceeding the depths at which the various types of shell begin to depart from vertically oriented fall. □

The molecular biology of immunoglobulin D

Frederick R. Blattner* & Philip W. Tucker†

* Department of Genetics, University of Wisconsin, Madison, Wisconsin 53706, USA
† Department of Microbiology, University of Texas Southwestern Medical School, Dallas, Texas 75235, USA

Immunoglobulin D (IgD) is co-expressed with immunoglobulin M (IgM) on the membranes of most B cells, yet its biological function has remained a mystery. Recent detailed information on the structure and transcription of the unusual IgD heavy chain (δ) gene in mouse suggests a complex genetic control. A model is presented for the developmental regulation of IgM and IgD and roles suggested for the membrane and secreted forms of IgD in the immune network.

VERTEBRATES respond to foreign substances by the production of antibodies, which are proteins consisting of two heavy and two light chains. In the higher vertebrates this response involves the sequential production of multiple classes of antibody with the same antigenic specificity but different effector functions. The effector or class of the antibody is determined by the constant (C) region of the heavy chain (C_H region). For the mouse, eight immunoglobulin classes have been identified: IgM, IgD, IgG3, IgG1, IgG2b, IgG2a, IgE and IgA; the H chains are designated with corresponding Greek characters and the genes encoding them are arranged in the order μ, δ, $\gamma 3$, $\gamma 1$ $\gamma 2b$, $\gamma 2a$, ε, α in a cluster spanning some 200 kilobase pairs (kbp) of DNA on chromosome 12 (reviewed in refs 1, 2). The light chains are encoded separately. The antigen-binding variable (V) region of the H chain is coded by a V_H gene that is assembled from separate *V*, *D* and *J* germ-line segments during B-cell ontogeny (for review see ref. 3). It is located to the left of the C_H cluster. A similar mechanism—but without *D* segments—applies to the light-chain variable region, which also contributes to antigen binding.

The primary response, elicited by the first exposure to an antigen, consists of antibody of the IgM class. The secondary response to the same antigen, however, involves the production of antibodies of different classes—IgG in serum and IgA in gut as well as IgM. Thus, between the primary and secondary responses, immune 'memory' for antigen is established. This is accompanied by a class switch in which the original V_H gene is expressed with a new C_H gene.

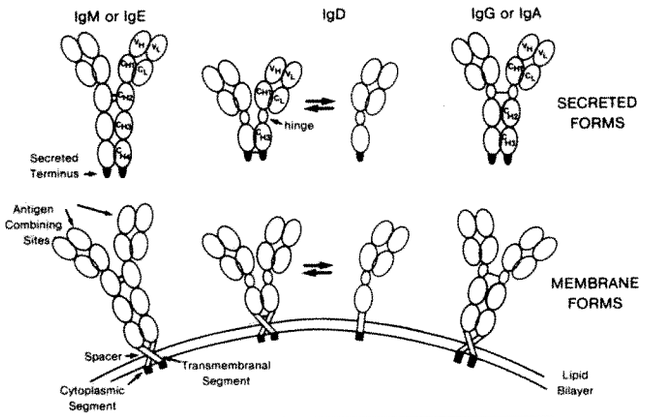
Antibodies are produced by B lymphocytes, each of which expresses immunoglobulin of unique antigenic specificity on its surface. Each immunoglobulin class can exist in both membrane-bound (m) and secreted (s) forms which differ in the carboxyl-terminal sequences of their respective H chains. One consequence of antigenic stimulation of a B cell is a shift of expression from the membrane-bound form to the secreted form which takes place without any change in either the specificity or the class of the antibody[4,5]. Thus, the surface immunoglobulin serves as an external signal of what the B cell, if stimulated, will produce. This is crucial for three reasons: first, it ensures that secreted antibody elicited by the interaction of membrane immunoglobulin with antigen will be appropriately directed; second, it permits B cells of the secondary response (memory cells) to be regulated as separate pools; and third, it allows maintenance of a repertoire of potential responses in the resting B-cell population at little metabolic cost.

IgD behaves paradoxically in relation to the above simplified view of the humoral immune response. It is a predominant surface immunoglobulin on most B lymphocytes[6,7], yet it is not secreted on antigenic stimulation of the cells that bear it[8]. What its role may be is a fascinating question, for elaborate mechanisms have evolved to make this immunoglobulin class behave oppositely to the others.

In this review we shall begin with a description of biological data about IgD and then summarize, from the molecular biologist's viewpoint, what has been learned about the δ gene. Next, the expression of the μ and δ transcription unit will be examined with an eye to understanding the mechanisms controlling RNA splicing in that system. Then, we shall make some suggestions as to how IgD may fit into the immune system. Although the predominant focus will be mouse, we shall also discuss the comparison between human and mouse structures, along with evolutionary implications.

Biology of IgD

IgD on the surface of B cells is co-expressed with IgM[9–12], but appears later[13,14] and is considered to be an indicator of the mature or 'virgin' resting B cell. On a given B cell, membrane IgD has the same antigen-binding specificity as IgM[15,16]. IgD antibody is a very minor component of serum (micrograms per ml compared with milligrams per ml for IgG)[17,18], so it seems unlikely that it has an important direct role in the neutralization of antigens. On the other hand, it can function as a receptor, for when heterologous antibodies against the μ or δ constant regions are used to mimic stimulating 'antigen', both stimulate replication[19–23]. When the cell is stimulated either in this way or with mitogens[24,25] or T-cell factors[26,27], IgM is synthesized and secreted whereas IgD production is shut off. This is consistent with the low levels of IgD but raises the question of how this regulation is achieved.



A controversial issue is the role of IgD in memory. Some hold[28,29] that the majority of cells giving rise to the secondary response have lost IgD from their surface, whereas others argue[30,31] that IgD loss is not a necessary stage in memory cell maturation.

Ablation of the population of B cells that carries IgD on their surface (IgD^+) by administration of heterologous anti-δ antibodies to the animal continuously from birth does not abolish the immune response[32]. This contrasts with the profound immunodeficiency engendered by suppression of IgM^+ cells with anti-μ antibodies[33,34]. This difference may simply be due to the fact that IgM^+ B cells are produced early in ontogeny and are precursors of most or all of the other cells involved in producing antibody, whereas IgD expression occurs after the B cell is competent to respond. IgD suppression *in vivo*[35] and anti-δ antibodies administered *in vitro*[36] do give rise to subtle shifts in the quantitative responsiveness of B cells to T-dependent antigens. This may indicate that IgD is involved in interactions

© 1984 Macmillan Journals Ltd

between T and B cells and in the regulation of B-cell populations.

Although the function of IgD remains obscure, some insight may emerge from the genetic and structural information that has recently begun to accumulate. These results reveal an unusual structure for the IgD protein, considerable complexity in its genetic regulation, and surprising species differences between man and mouse.

Class	IgM	IgD	IgG3	IgG1	IgG2b	IgG2a	IgE	IgA
H chain	μ	δ	$\gamma 3$	$\gamma 1$	$\gamma 2b$	$\gamma 2a$	ε	α
Number of Domains	4+V	2+V	3+V	3+V	3+V	3+V	4+V	3+V
Hinge	0	35	17	13	22	16	0	14
Spacer	12	26	17	17	17	17	18	25
Transmembranal Segment	26	26	26	26	26	26	26	26
Cytoplasmic Segment	3	3	28	28	28	28	28	14
Secreted Terminus	20	21	2	2	2	2	8	20

Fig. 1 Structure of membrane (m) and secreted (s) mouse immunoglobulins. The constant regions have from two to four domains depending on class, and in some cases a hinge segment is present between the first and second constant region domains. This is thought to introduce flexibility into the structure to allow the antigen binding site to achieve better contact with antigen[96]. Shown at the top are the monomer s forms (H_2L_2) for the three structural types as well as the IgD half-monomer forms (shown in equilibrium with the monomer by arrows). Large and small ellipsoids represent domains and hinge regions, and dark ellipsoids represent the secreted carboxyl termini of the H chains. Non-covalent domain contacts are shown by the overlaps, and covalent H–H disulphide bonds by straight lines. Below, the three immunoglobulin types are illustrated attached to a B-cell membrane. Most of the molecule (including the antigen binding site constant regions and m-form specific spacer region) is on the outside of the lipid bilayer. The transmembranal segment spans the membrane and the cytoplasmic segment (box at the C-terminal end) protrudes inside. At the bottom of the figure is a structural summary for s and m forms of the eight mouse H chains. All numbers, except for domain numbers, refer to amino acids. Specific references used are: μ[42,43], δ[37,38], $\gamma 3$ (J. Wells *et al.*, in preparation), $\gamma 1$[102–105], $\gamma 2b$[103,104,106], $\gamma 2a$[105,107], ε[108,109] and α[109–110]. [A discrepancy between the genomic[37,38] and cDNA[37] sequences in the secreted terminus and an uncertainty in the position of the beginning of the $C_\delta 1$ domain have been resolved through analysis of peptide sequences[95] of murine δ protein. In other respects, the DNA sequence was confirmed by the peptide analysis. Thus the sequence of the myeloma protein can be considered to be quite solid. There is no proof that the secreted terminus of the myeloma protein is the same as the terminus of serum δ found in minute quantities in the normal animal. The structure of the membrane form[38] was established entirely from genomic DNA sequence using realistic, but unproven, assignments for the membrane exon boundaries. This structure has been confirmed in part by the demonstration that an anti-peptide antibody against the membrane spacer will precipitate δ-chain obtained from the surface of normal spleen cells (T. Shinnick, F.R.B. and P.W.T., unpublished observations). However, further protein analyses will be desirable to ensure that all splice boundaries have been correctly established.

The unusual IgD protein

Through DNA sequence analysis we now know the structure of the δ gene and hence the amino acid sequence of the δ protein of the BALB/c mouse (summarized and compared with other H chains in Fig. 1). The outstanding feature of the molecule is that whereas the constant regions of other H chains have three or four domains, δ has only two[37]. These domains, termed $C_\delta 1$ and $C_\delta 3$ (C_{H1} and C_{H3} in Fig. 1) by homology with other classes, are separated by a unique hinge segment which is quite long and lacks the cysteine residues that normally provide the links between the two H chains in the standard H_2L_2 subunit structure of immunoglobulin. However, both the membrane spacer region of the membrane-bound form of δ protein and the secreted terminus of the secretory form of δ protein have a cysteine which could cross-link the respective chains[38]. The presence of both IgD monomers (H_2L_2) and IgD 'half-monomers' (one H chain and one L chain) on B-cell membranes, has been well documented[39,40], and there seems to be an equilibrium between the two forms on the cell surface. It is not known whether the secreted form exists in the same sort of equilibrium, although the H_2L_2 form has been demonstrated electrophoretically[41]. The transmembrane segment of δ is very similar to that of μ, and the carboxyl-terminal residues that extend into the cell are identical[38,42]. On the other hand, the portions encoded by membrane exons that might lie just external to the cell-surface (spacers) differ radically in length and amino acid composition. This structural dichotomy may bear on whether antigenic stimulation through μ or δ gives the same cellular response.

The μ–δ gene locus

The detailed genetic map of the μ–δ region is shown in Fig. 2. The four constant region exons of the C_μ gene, including the secreted terminus (coded as part of the $C_\mu 4$ exon and membrane terminal exons $\mu_m 1$ and $\mu_m 2$) are located within a span of 4 kbp of DNA[42–45]. The δ gene begins 2 kbp beyond and spans a much larger area (10 kbp)[38,46–49]. The δ gene is unique in that both the membrane and secreted termini are separated from the body of the gene by a large (5 kbp) intervening sequence[37,38,46,48]. In between δ_s and $\delta_m 1$ is a potential third carboxyl-terminal exon, termed δ_x (ref. 38), which has not been demonstrated to be translated into protein but which would encode a peptide with the hydrophilic characteristics of a secreted terminus.

In the course of B-cell differentiation these exons are differentially expressed. The first clue to how this is achieved came from analysis of B-cell tumours or hybridomas, which have served as models for resting B cells. The two lines studied in greatest detail are the BCL_1 lymphoma[50], which arose spontaneously in a BALB/c mouse, and the GLC28 hybridoma[51], which was made by fusion of a hamster lymphoma to a mouse B cell. The BCL_1 tumour maintains many of the characteristics of resting B cells including the ability to secrete IgM after stimulation with lipopolysaccharide[52]. The GLC28 hybridoma retains characteristics of the hamster parent, including expression of hamster immunoglobulin[48], but both tumours clearly express murine IgM and murine IgD on the cell surface[48–53].

In each of these cell lines, both μ and δ constant regions are expressed with the same V_H gene[48,49], and that V_H gene remains immediately 5′ to the μ gene in cells producing IgD (see Fig. 2*b*). Thus, δ must be expressed from an RNA precursor containing both μ and δ and from which the μ gene is spliced out.

Myelomas

A well studied cellular model for the immunoglobulin secreting, terminal stage of B-cell differentiation is the myeloma. Analyses of many examples led to the discovery that the expression of the secreted forms of all immunoglobulin classes except for μ is invariably associated with the deletion of DNA (including μ), juxtaposing the expressed class with the V region. These deletions are mediated by recombination between 'switch sites'[1,2] located immediately 5′ of each of the C_H genes except for δ[54,55] (Fig. 2) and the process is termed class switch recombination.

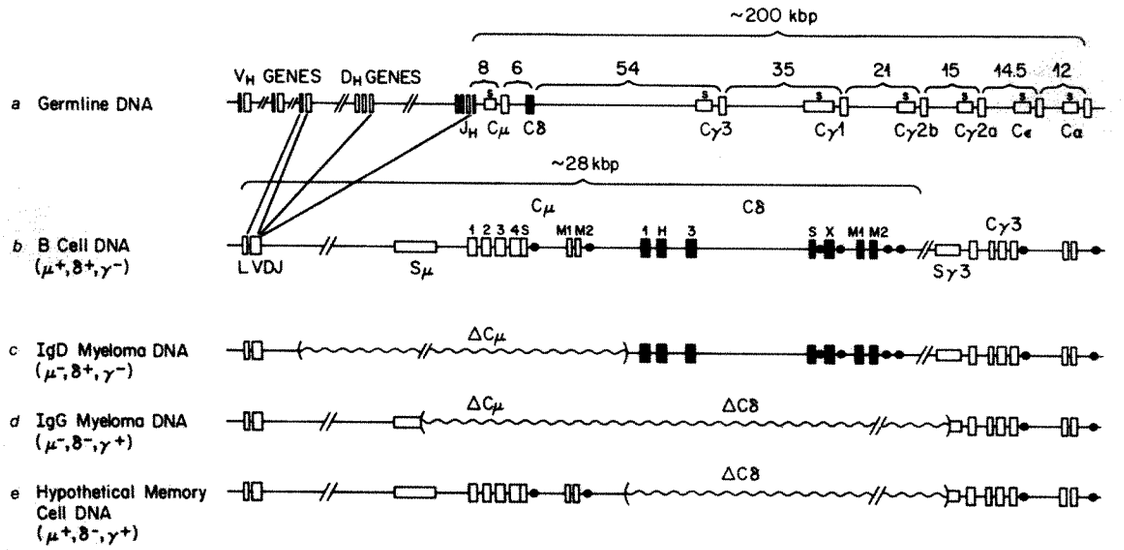


Fig. 2 Immunoglobulin gene arrangement and rearrangement during development. Tall boxes are protein encoding regions (δ regions are always in black), thin boxes are switch (S) recombination sequences, and dark dots are transcription (*end*) sites (see text). Unless indicated (//), distances are drawn to the scale. *a*, Map of the germ-line (unrearranged) H-chain locus. Distances, where indicated in kbp, are from centre to centre of a gene (for simplicity shown as a single box) or gene cluster. Switch sites are located 5′ to all C_H genes except C_δ. *b*, Expanded map of the μ–δ transcriptional unit in B-cell DNA. As indicated by the lines from *a*, only the variable region segments (V_H, *D* HHand *J*) are rearranged in cells expressing IgM (μ-chains) or IgM and IgD (δ-chains) simultaneously. Here and in *c*–*e*, exon fine structure is shown (see text for details). *c*, IgD-secreting tumours delete (Δ) C_μ. The approximate length of the deletion (determined in this case from the myeloma TEPC 1017) is indicated by a wavy line, and the left and right recombination points are represented by parentheses. Note that this deletion does not utilize conventional switch sites (see text). *d*, IgG-secreting cells delete all genes between *V*–*D*–*J* and the expressed (in this example, γ3) gene. Conventional switch sequences are utilized. *e*, Hypothetical DNA rearrangement for putative double-producing ($\mu^+\gamma3^+$) memory cells. The proposed deletion occurs at a recombination site 3′ to C_μ and 5′ to at least part of $S_\gamma3$, thereby deleting C_δ and providing a reasonably short transcriptional unit for μ–γ membrane expression.

The switch site regions are composed of tandemly repeated pentamers: GAGCT mixed with GGGGT[1,2,56] and similar variants. The boundaries of the deleted DNA are near, but not necessarily within, the switch site repeat[1,2,57,58]. Despite the absence of a δ switch site, examples of IgD-secreting myelomas have been found[41,46,59,60]. In these cases, deletion of C_μ has also occurred. In the one case so far examined, TEPC 1017 (ref. 55 and A. C. Gilliam, A. Shen, J. F. Mushinski, F.R.B. and P.W.T., in preparation), the deletion endpoints were not anywhere near sequences that resemble switch sites. Thus, in rare cases rearrangements can occur that activate IgD secretion but which are not mediated by switch sites. It is not clear, however, whether such deletion is related in any way to the biological mechanism of secretory expression of IgD. Since membrane IgD expression in B cells does not involve DNA deletion[48,49], we suspect the secretory expression is also controlled at the transcriptional level. Therefore, non-switch rearrangement may be an artefact limited to the transformed cells.

μ–δ RNA analysis

Additional information has been obtained by direct analysis of lymphocyte RNA. Table 1 lists the most important mRNAs and the cells in which they have been detected. The putative structures of precursors of some of them are shown in Fig. 3 (for details see figure legends).

Initiation of H-chain transcription begins at a promoter located just upstream of the active *V* gene[61]. So in a given B cell, as far as is known, all the H-chain RNAs have the same 5′ end. The principal H-chain RNAs of the B cell are the membrane forms of μ and δ. In both the μ and δ myelomas, the secreted forms predominate, although membrane RNA is also synthesized. Several minor components not illustrated in Fig. 3 are described in the legends to Table 1 and Fig. 3. Thus, depending on its state of differentiation, the B cell can produce multiple forms of mRNA from the same DNA, each with a different 3′ end and spliced in a unique pattern so that in some cases what is an intron in one RNA is an exon in another.

The donor and acceptor RNA splice sites at the ends of the immunoglobulin intervening sequences are typical of those of other gene systems[62] and immunoglobulin splicing appears to be no less accurate. Specifically, there is no noticeable tendency for the splicing apparatus to skip correct splice sites, thereby deleting exons from the message. This despite the fact that the μ–δ genetic region contains many sequences that are similar to the donor and acceptor splice sites of the exons which are not used as splice sites as far as is known. Control of splicing is thus as much a matter of avoiding incorrect splicing choices as of choosing the correct sites; and the pattern must be altered according to the state of cell differentiation.

Control of splicing

The study of adenovirus (reviewed in refs 63, 64) has shown that a critical step in determining differential expression of the late genes is the selection of the 3′ end of the mRNA precursor. This is thought to occur by endonucleolytic cleavage of the precursor, with possible exonucleolytic trimming[65,66], followed by addition of polyadenylate [poly(A)] residues to the 3′end. RNA splicing to remove intervening sequences generally follows both clipping and polyadenylation[63,65,67].

It is not known what structural feature of the precursor RNA determines the position of 3′-end clipping, so we have adopted the neutral term '*end* site' for this hypothetical complex recognition element. The sequence AATAAA[68] or AATTAAA[69] that occurs near the 3′ end of most eukaryotic mRNAs may be a component of the recognition site. However, these sequences occur at 16 places in the μ–δ region and only 6 are (apparently) used (J. E. Richards, unpublished data). The locations of the six functional *end* sites of the μ and δ transcripts are indicated in Figs 2–4.

It has been proposed that control of expression of the membrane as opposed to the secreted forms of IgM[42], as in adenoviruses, is controlled at the level of 3′ end selection (end_1 versus end_2 in Fig. 3). In support of this model, a recent analysis[70] of nuclear RNA in early B-cell tumours has directly demonstrated the first two predicted μ precursors of Fig. 3.

Choice of splice sites may follow automatically from choice of *end* sites. In the case of μ, the splicing choices are simple. The last three splice sites are missing from the shorter transcript

(Fig. 3), so they cannot be used and the S terminus is coded as an extension of the $C_\mu 4$ exon. The choice in the IgD myeloma TEPC 1017 is also simple. end_1 and end_2 are deleted from the DNA (Fig. 2*c*), thereby allowing straightforward expression of the δS mRNA from end_3. Membrane or secreted IgD expression in B cells is more difficult to understand for it requires removal of μ sequences from a long δ mRNA precursor containing both μ and δ exons. Thus the splice sites of μ, which must not be skipped in the μ transcript, most definitely must be skipped in order to produce δ mRNA.

In these more complex cases, how might the selection of splice sites be made? One possibility would be a developmentally regulated change in the specificity of the splicing apparatus, but this assumes sequence differences in the splice sites that might be differentially recognized, and a computer search (F.R.B., unpublished) has not suggested such differences. We would therefore like to propose that RNA precursors of different lengths might adopt different secondary structures, so exposing alternative splice sites to the splicing machinery. The developmental regulation of heavy-chain gene expression could in this case be simply a matter of regulation of 3′ *end* site selection. According to the model of Fig. 4, 3′ *end* site selection could be regulated simply by alterations in the level of the enzyme ('endase') that cuts the RNA precursor at the *end* site. Since an RNA molecule must survive a cross fire of endonuclease cutting to reach full length, we dub this the 'gauntlet' model. We assume that endase is present in the resting B cell in limiting amounts. The level of expression of various 3′ ends in B cells, then, would depend on the relative affinities of different *end* sites for endase. To account for the mRNA abundances discussed above and in the legend to Table 1, we have postulated the relative strengths of *end* sites—as shown in Figs 3 and 4.

In the differentiation of a B cell to a secreting cell, we propose that the quantity (or activity) of endase is increased. The effect would be to force the usage of more 5′ (promoter-proximal) *end* sites, regardless of affinity, because the first cut defines the end of the RNA regardless of any downstream cuts (gauntlet effect). In the limit this would drive the system to produce only the shortest possible precursor RNA in the fully differentiated plasma cell. It would also permit a continuous progression from resting B cell to plasma cell rather than an abrupt jump, which could help explain how IgM antibodies can be secreted by B cells (blasts) that have not become fully differentiated into plasma cells. The model also explains why, in all myelomas, the most strongly expressed mRNA is the one that is defined by the first *end* site in the DNA after the promoter, and why the switch site recombination is needed to obtain efficient expression of downstream classes in myelomas.

Other observations which this model helps to explain are: (1) The wide and continuous variations of μ to δ ratios observed in B-cell populations[71,72]. (2) The transitory nature of IgD expression on the resting B cell and its disappearance on activation[24–27]. (3) The observation (ref. 73 and D. J. Kemp, personal communication) of an RNA fragment containing only μ_m sequences whose size corresponds roughly to the end_2 to end_3 interval. Such '*end–end*' fragments would be expected if the RNA polymerase continues down its DNA template beyond the first *end* site, as suggested in adenovirus[63,64], and the endase nicks the downstream *end* sites as well. (4) The observation[74] that neonatal B cells seem to produce some secreted IgM. This could be due to an intermediate level of endase in these very early B cells.

An aspect of immunoglobulin expression that is not easily explained by the gauntlet model is the expression of downstream classes (IgG, IgE or IgA) in memory B cells, if these are coded from an RNA precursor up to 200 kbp in length as has been reported[75].

Selection of 3′ ends by cutting of RNA precursors at *end* sites clearly is only one of several levels at which immunoglobulin expression is regulated. Others include control of transcription initiation, possibly involving enhancer-like elements[76–78], transcription termination and chromatin structure alterations[74].

Table 1 Classification of μ and δ mRNAs

3′ Terminus	Size (kb)	Name	Occurrence
end_1	2.4	μ_s	Spleen and B-cell tumour (weak), μ myelomas (stro
end_2	2.7	μ_m	Spleen and B-cell tumour (strong), μ myelomas (we
end_3	1.75	δ_s	δ myelomas (strong)
end_3	3.2	δ_s	Spleen, B-cell tumours an myelomas (very weak)
end_4	2.65	δ_x	Spleen and B-cell tumour (weak) δ myelomas, (very weak)
end_5	2.1	$\delta_{m\text{-}minor}$	Spleen and B-cell tumour (weak), δ myeloma (very weak)
end_6	2.9	$\delta_{m\text{-}major}$	Spleen and B-cell tumour (strong), δ myelomas (we
end_6	2.9-	$\delta_{m\text{-}major}$ + 3′ heterogeneity	Spleen and B-cell tumour (very weak), δ myelomas (very weak)
end_2	2.0	μ_m 3′ fragment	μ myelomas and T cells (weak)

Sizes of the end_3, end_5 and end_6 δ mRNAs listed above[59,98] also measured as 1.6 (ref. 47) and 1.8 (ref. 48), and 2.7 (refs 47 respectively. The 2.4-kb μ_s and 2.7-kb μ_m mRNAs that were orig described in IgM-secreting myelomas[42,44,45] correspond to *end* end_2. These RNAs are also observed in splenic B cells[99]. The qu of μ_s form mRNA is considerably reduced when large spleen cells (l and plasma cells) are selectively removed (D. Yuan, unpubl observations). A number of 'sterile' μ RNAs, lacking some e component required for normal translation, have been observed i cytoplasm of both B and T cells[100,101]. In all δ^+ or $\mu^+\delta^+$ examined[48,59,98], two forms of δ mRNA are found, which we term as $\delta_{m\text{-}minor}$ and $\delta_{m\text{-}major}$ according to their relative abundance. terminate at end_5 (~2.1 kb) and end_6 (~2.9 kb), respectively. 10–50-fold difference in level of expression between these form may be due to differences in the strength of termination. These mR apparently code for the same protein[38] and differ only in the len the 3′-untranslated region. The $\delta_{m\text{-}major}$ form also shov heterogeneity caused by removal of intervening sequences with 3′ untranslated region of some molecules but not others[38,48].

The 1.75-kb transcript for δ_s, ending at end_3, is strongly exp only in the IgD-secreting tumours from which the μ gene has deleted at the DNA level[47,48,59,98]. In spleen cells and B-cell tun the only RNA that can be found ending at end_3 is a 3.2-kbp spe This species, however, is a true B-cell product since it is enrich the small B-cell population (D. Yuan and P.W.T., unpublished re No information is yet available as to its splicing pattern, nor is it whether this RNA codes for δ_s of the myeloma type. Also fou spleen and B-cell tumours is an RNA of 2.65 kb ending at *end* 38, 98). This RNA may code for δ_x, although there is no eviden this terminus being used in a protein. Either the 3.2-kbp or 2.6 RNAs might be unspliced precursors and thus might not be *bor* mature mRNAs.

There is also an indication that post-translational regu occurs in this system, since 10-fold less δ mRNA than found in the cytoplasm of splenic B cells which have amounts of the Htwo proteins on their surfaces[80].

Elucidation of the relative importance of these mecha will require detailed analysis of RNA in a variety of ty cells. We have recently observed substantial δ specific R nuclei of neonatal B cells that are expressing μ but not the surface (unpublished data of D. Yuan and P.W.T.) RNA could reflect *end–end* fragments as predicted by the let model. Such RNA is not found in myelomas commit IgM, however. This may indicate that transcription termi at a site between μ and δ comes into play in fully differen plasma cells.

The role of IgD

IgD is different from other immunoglobulins in structure arrangement, physiological localization and in its behavi the immune response. Yet we have no idea of its fun

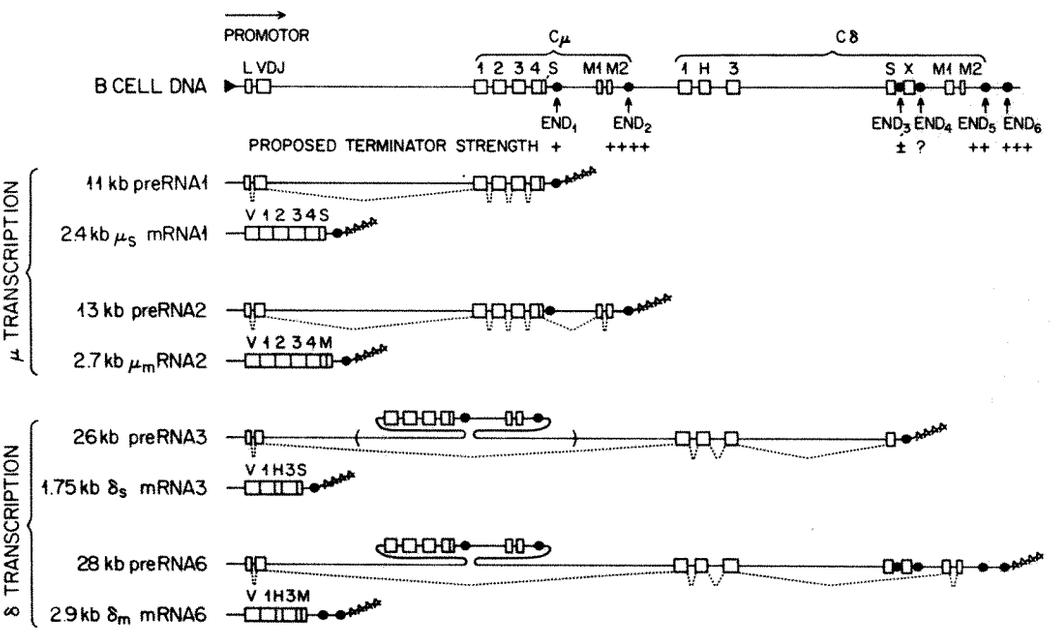

Fig. 3 Transcription and splicing patterns of major μ and δ mRNA precursors. A detailed scale map of the μ–δ transcriptional unit including the promoter (►) is given at the top (also see Fig. 4 legend). The relative strengths, based on mRNA abundances (see Table 1 legend) of transcription *end* sites are indicated below each one with +. RNAs are shown as precursor (preRNA)–product mRNA pairs. Sizes of the preRNAs are predicted from the DNA sequence, assuming that 3′-end termination results from RNA cleavage (see text for details). Sizes of the mRNAs have been determined experimentally. Splicing is indicated by dotted lines and poly(A) tails are shown as AAAA. Splicing of the μ- and δ-containing preRNAs 3 and 6 to yield exclusively δ mRNA products may depend on eliminating the μ sequences from the splicing complex through local secondary RNA structures (simplistically illustrated in the figure by a total looping out of μ). In δ-expressing myelomas, the C_μ gene and its associated *end* sites are already removed by DNA deletion (denoted by parentheses on the preRNA3). See text for references.

Perhaps it simply serves as an auxiliary antigen receptor on the B cell[22,23,81], but this seems a rather trivial explanation for the evolution of such a complex system. We prefer to suppose that it has a role in regulation of B-cell populations, because this would help explain the paradoxical aspects of IgD expression. (A third possibility, of course, is that it has no function.) Since IgD appears on the mature virgin B cell and decreases when the B cell is stimulated by antigen, the virgin cell would be the one in whose regulation IgD would be likely to participate.

These cells arise by differentiation from stem cells of the bone marrow or fetal liver in a process that involves random generation of variable regions from the germ-line V gene segments, thus producing cells with the antigenic specificities that represent a sampling of the entire repertoire of V_H regions that can be constructed from the germ line. B cells have an average lifetime of a few weeks, so their population is constantly turning over. The pool is depleted by cell death and fed by the influx of virgin cells plus replication of cells that may be stimulated by antigens or other regulatory influences which may be responsible for maintenance of immunological memory at the B-cell level. One way of accounting for the persistence of memory cells is through the network theory[82], in which antibodies themselves function to regulate the distribution of V regions represented in the B-cell population by binding to idiotypic determinants of surface immunoglobulin on B cells so as to affect differentially the replication of B cells expressing various determinants. Class-specific and/or idiotype specific factors produced by T cells play the part of regulators in modern formulations of the network theory[83–86].

IgD and especially its spacer segment (Fig. 1 and ref. 38) would be well suited to serve as a receptor on the B cell for the class-specific component of the network influences regulating the primary response. Since IgD expression is shut down on antigenic stimulation, this marker could serve to focus these influences specifically onto the virgin B-cell population. Presumably, the spacers of other membrane immunoglobulins could serve the same role for regulation of the other classes. The reason the spacer in particular is proposed for this function is that it is encoded on the same exon as the transmembrane segment (also true of other immunoglobulins). Thus, this determinant cannot appear on the surface of a cell by cytophilic adsorption of serum antibody nor could serum antibody compete for sites with a factor directed against the spacer portion.

It is more difficult to account for the secreted form of IgD (either δ_s, δ_x or unknown terminus). However, secreted IgD could complete a feedback loop by supplying afferent signals representative of all the idiotypes present in the B-cell repertoire to the T-cell population. This role would fit with the prediction of the gauntlet model that the s form of IgD would be secreted from resting B cells, not IgM-secreting ones. The low stability of serum IgD[22] would also serve a function, since an intercellular messenger molecule should not have an excessive half life if it is to function properly in that role. There is, in fact, some evidence that a factor emitted by B cells is needed for the development of a class of isotype-specific T_H cells[87]. This factor might be the s form of IgD.

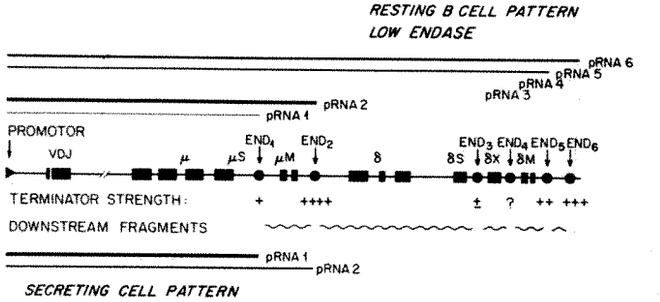

Fig. 4 The gauntlet model for modulation of μ–δ transcription. The μ–δ B-cell transcriptional unit is shown in the centre with exons as boxes and 3′ *end* sites as dots (see Fig. 3 legend). All primary transcripts (preRNA 1–6) initiate at the promoter (►) left of V–D–J and terminate at *ends*[1–6] as indicated by the relative length of the lines. The relative abundances of the preRNAs, reflected by experimentally observed abundances of their mRNA products (Table 1 and its legend) are indicated by the thickness of the lines. The model predicts that in the resting cell (top of figure), the enzyme (endase) that cleaves the preRNAs at *end* sites is in low concentration. Since fewer molecules are cleaved, longer transcripts (membrane forms) would predominate with their relative abundances weighted by *end* sequence affinities (+) for endase. On activation to secretion (patterns at the bottom of the figure), the endase activity and/or concentration is increased dramatically, resulting in almost complete dominance of promoter-proximal *end* sites regardless of affinity. The wavy lines represent hypothetical *end–end* fragments.

Human and mouse IgD

The human δ protein chain, sequenced from myeloma material[88–91], does not show all of the oddities of the mouse molecule. The human chain is conventional in having three rather than two constant region domains. Its hinge is even longer than the murine one and contains a bizarre cluster of charged amino acids in its C-terminal portion, as well as a cysteine residue that could be used for normal inter-H-chain linkage.

The sequence match between murine and human IgD molecules is poor in the first domain (~33% amino acid match). Only the third domain, exclusive of the secreted terminus, has the high degree of homology (52%) expected for corresponding structures.

The human δ gene has been cloned and a fragment sequenced to show that its position in human DNA is analogous to that in the mouse[92]. However, the disappearance of an entire domain in the mouse clearly represents a dramatic evolutionary difference that raises a serious question about whether the two molecules could serve the same function (or any function) in the two species. Could the apparent loss of a domain result from a technical artefact? We think that this is unlikely because data for rat[93,94] and another strain of mouse[95] indicate that both have the same two domain δ-chain structure that we deduced for BALB/c[37,38]. Moreover two independent human δ-chains have been sequenced with identical results. It seems that there must have been a dramatic divergence in the δ gene after the separation of human from rodent evolutionary lines.

It is unclear how these differences should be interpreted. Logic would indicate that the second domain is not important to IgD function, and would focus attention on the third domain or possibly the spacer segment, whose sequence is unknown in man. On the basis of recent studies of domain deletion mutants (V. Oi, personal communication), there is reason to believe that the absence of a $C_\delta 2$ domain may not cause extensive disruption of general immunoglobulin folding patterns[96]. In any event, the existence of IgD in seven species (ref. 97 and refs therein) probably indicates that the molecule must have conferred a significant advantage over evolutionary time.

We thank J. Richards, A. Shen, F. Mushinski, C. Word, A. Gilliam, J. Wells, D. Yuan and T. Shinnick for providing data before publication, J. Uhr, D. Capra, C. Janeway, R. Schwartz, V. Oi, W. Paul and M. Wabl for suggestions on the manuscript, D. Odle for the art work and N. Peterson and M. Allan for secretarial assistance.

A survey of Ethiopia's Middle Awash Valley in 1981 yielded new and significant archaeological, palaeontological, geological and geochronological results. Included in the new discoveries are hominid fossils from the Pliocene which show primitive cranial anatomy and a femur adapted to bipedality. Archaeological records document human technological change spanning the past 1.5 Myr.

RESEARCH into Africa's rift system has elucidated critical stages of human technological and physical development, providing data on environments, behaviour and phylogenetic relationships of extinct hominid species. The 1981 survey of Ethiopia's Middle Awash Valley resulted in new discoveries and confirmed the importance of the region for human origins research.

The study area is situated along the Awash River Valley between the site of Hadar in the north and the town of Gewane in the south. Miocene, Pliocene and Pleistocene deposits crop out along both eastern and western valley margins as well as in the basin centre. Geologist Taieb discovered the palaeoanthropological significance of the region during geological reconnaissance in the 1960s[1]. In 1971 and 1972, Taieb, Johanson, Coppens and Kalb conducted a preliminary survey of the central Afar. They formed the International Afar Research Expedition (IARE) and began to investigate Hadar. Discoveries there yielded new insights into hominid evolution[2,3].

The Middle Awash was explored between 1975 and 1978 by Kalb's Rift Valley Research Mission in Ethiopia (RVRME). Small excavations were done and a partial hominid cranium was found in Middle Pleistocene deposits at Bodo[4]. Taieb's initial work had identified sediments along the Awash ranging between Pliocene and Quaternary[1,5]. The RVRME conducted the initial mapping and palaeontological work here. Biostratigraphical data indicated prolonged deposition[6–10].

Wendorf, an RVRME member, invited one of us (J.D.C.) to join the archaeology team in 1977 and in 1981 the Ethiopian Ministry of Culture invited J.D.C. to lead a multidisciplinary team to the Middle Awash. Two months were spent in the field examining localities in the western, central and eastern sectors of the study area. Abundant archaeologocal remains ranging from later stone age to Oldowan were identified. Biostratigraphical analysis confirmed that approximately 6 Myr of vertebrate evolution is represented within the study area. A programme of tephrostratigraphy was initiated and the first radiometric dates for the Middle Awash strata were obtained.

Stratigraphy

Exposure of sediments in the area is often good. However, lateral correlation is hindered by common NNW–SSE and NNE–SSW normal faults that dissect the deposits and bring rocks of different age into fault contact. Lithological correlation is further impeded by erosional gaps within the sequences and between the areas. Lateral facies changes and the repetitive nature of the late Neogene sedimentation complicate the geology. For these reasons the numerous volcanic horizons provide essential stratigraphical and chronological control. Kalb *et al.*[7,9] recently formalized sedimentological groups, formations and members for the entire Middle Awash area. We refer to these units below but prefer to work with the previously introduced, informal stratigraphical nomenclature[6] until tephrostratigraphy clarifies formational boundaries in the region. Our 1981 survey showed that an east–west geological transect across the Bodo and Dawaitoli areas provides a useful guide to the general stratigraphical and tectonic relationships of Plio-Pleistocene deposits of the eastern sector of the Middle Awash (Figs 1 and 2). The 1981 archaeological and palaeontological discoveries reported here are either within or firmly correlated to the stratigraphical sequence at Bodo.

Deposits that crop out closest to the Awash in the eastern sector consist mostly of sterile brown clays and silts but include additional interbedded strata in the Bodo, Dawaitoli, Hargufia and Meadura catchments. These strata, the Upper Bodo Beds of Kalb *et al.*[6] are particularly rich in Middle Pleistocene artefact assemblages and fauna. Work on volcanic horizons in these beds should help to clarify relationships between the Bodo, Meadura and Dakanihyalo members of the Wehaietu Formation formalized by Kalb *et al.*[9].

Lower Pleistocene sediments found in the Bodo area are structurally separated from the Middle Pleistocene outcrops by normal faults, downthrown to the west. Similar structural relationships are observed between Pliocene and late Pliocene/Lower Pleistocene rocks at Dawaitoli, Wilti Dora and Matabaietu. The Lower Pleistocene beds at Bodo, the Middle Bodo Beds of Kalb *et al.*[6] (Matabaietu Formation[9]) consist of brown clays interbedded with both unconsolidated and calcite-cemented sands and gravels. The cemented sands are richly fossiliferous and at least three volcanic tuffs are interbedded in the sequence.

Pliocene deposits exposed in the Bodo area are >70 m thick and constitute the Lower Bodo Beds of Kalb *et al.*[6] (Sagantole Formation, Beearyada and Kalaloo Beds[9]). Seven tuffaceous units were identified in the composite section and one of them, informally termed the Cindery Tuff (CT), was used as a primary chronostratigraphical marker horizon (Fig. 2). This tuff is a 15–30-cm thick, grey lapilli tuff. It is a primary plinian ash deposit that, in hand sample, shows grey pumice clasts, clear grey glass shards and scoracious black glass fragments ranging from sand-size particles (1.0 mm) to fine, granule-size particles

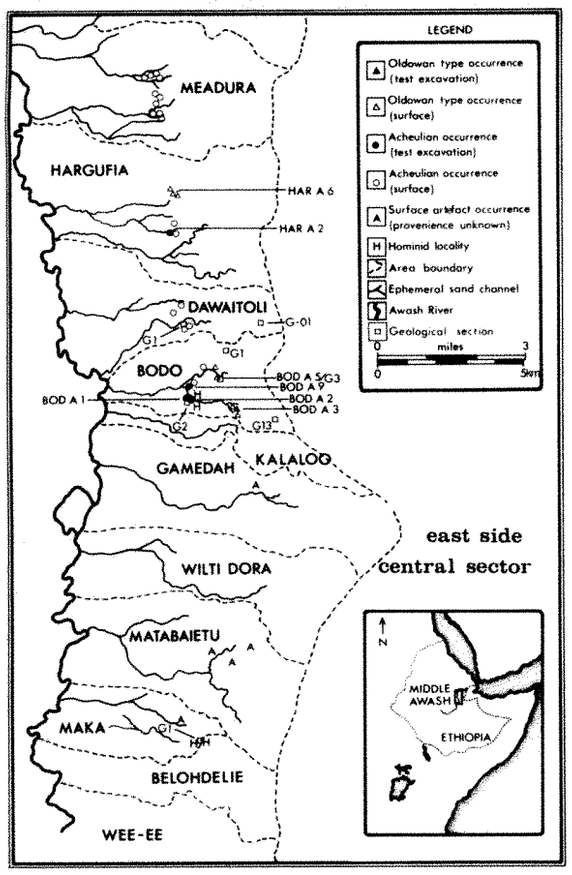

Fig. 1 The central eastern sector of the Middle Awash study area.

(up to 5.0 mm). The CT crops out extensively at Bodo and appears to have erupted into a very shallow, laterally extensive, freshwater lake, probably not highly alkaline. The description of "... a widely traceable coarse or lapilli tuff (10–35 cm)" at the base of the Kalaloo Beds[7,9] is here interpreted as the only previous description of the Cindery Tuff. Mammalian footprints found impressed into the upper CT surface at Gamedah suggest shallow lake conditions, possibly the lake margin. We have already traced the CT over a distance of ~30 km from Wee-ee to Meadura (Fig. 1).

Petrographic studies and microprobe geochemistry show that the CT is a primary ash deposit, not reworked, and containing no obvious detrital phases. The $^{40}Ar/^{39}Ar$ analyses performed on CT feldspars and glasses are concordant, yielding ages of 3.9–4.0 Myr. These results are corroborated by preliminary zircon fission track age estimates conservatively set at 4.0 ± 0.2 Myr. An isotopic age concordance of 4.0 Myr for the CT is thus a reasonable assessment of its eruptive age, and age consistent with biostratigraphic findings of the 1981 fieldwork and previous analyses[12,13].

Outcrops exposing the CT are among the most laterally continuous of this age known in Africa. At least 50 m of horizontally bedded silts, clays, diatomites, lenses of fossiliferous sand and gravel and occasional bands of volcanic ash, limestone and lignite lie below the CT. The sections beneath the CT are lithologically uniform from Wee-ee to Bodo. Diatomite is common in the upper 20 m of sediments beneath the tuff where 1–6 m thick diatomite beds alternate with grey-brown clays of comparable thickness. Facies changes are more common above the CT. Approximately 20 m of sediment overlie the CT in the Maka area. These include a vitric tuff and fossiliferous, yellow-orange stained gravel-sands. The cross-bedded sands and gravels alternate with subhorizontal silts and clays above the CT and indicate a major contrast to deposition below the tuff—a contrast which persisted during Lower and Middle Pleistocene times. Tectonic events were probably responsible for the demise of Miocene and early Pliocene lakes in the area[11].

Archaeology

Taieb[1] was the first to record artefacts coming from Plio-Pleistocene sediments in the central Afar. Kalb *et al.*[8,14–16] have also reported the existence of numbers of archaeological sites in the Middle Awash yielding stone artefacts of Oldowan, Acheulian, Sangoan and later age and have published accounts of two of these[15,17]. Corvinus and Roche[18,19] recorded Oldowan-type artefacts from conglomerates of the upper beds of the Hadar Formation in the Gona River Area. Harris[20] has subsequently test excavated and described an occurrence of Oldowan artefacts and bone *in situ* in fine-grained sediments in the Gona catchment; these, it is suggested, might be nearly 2.4 Myr old.

Our own survey concentrated on sediments of Upper Pliocene (Lower Bodo Beds[6]; Matabaietu Formation[7]) and Lower and Middle Pleistocene (Middle and Upper Bodo Beds[6]; Wehaietu Formation[7]) ages, situated on the east side of the Awash between the Maka and Meadura catchment areas and also at Dakanihyalo on the west side of the study area. Oldowan assemblages were found eroding from overbank silts in the Middle Bodo Beds[6] exposed in the Ounda Bodo catchment. Typologically Lower Acheulian occurred in a lag gravel capping Pliocene sediments at Maka and in fossiliferous fluvio-lacustrine sediments at Dakanihyalo. Numerous occurrences as previously reported by Kalb *et al.*[8] were found eroding from Middle Pleistocene (Upper Bodo beds[6]; Wehaietu Formation[7]) channel sands and silts. Two of the Oldowan and four of the Acheulian sites were test excavated.

Oldowan

Kalb *et al.*[8] have reported Oldowan artefacts eroding from Lower Pleistocene sediments at Wilti Dora but, in spite of close search, we were unable to locate any *in situ* artefacts although heavily patinated choppers and flakes traced to an overlying lag gravel lie on the slopes in some places. At Matabaietu, where a surface Oldowan occurrence had previously been reported[15], the 1981 survey found small numbers of heavily patinated artefacts on the surface and close to the bones of elephant and hippopotamus. This association could be fortuitous resulting from deflation so that, until stratified archaeological occurrences are discovered and excavated, the designation of Matabaietu as an Oldowan locality must remain uncertain.

We were, however, fortunate in locating in the Bodo drainage five Oldowan occurrences. These are the earliest stratified occurrences of stone artefacts found in the Middle Awash so far, although older occurrences can be expected. The assemblages, characterized by small cores and flakes with occasional retouched pieces, show morphological and technological similarities to Plio-Pleistocene stone artefact occurrences assigned to the Oldowan Industrial Complex found just to the north at Hadar and elsewhere in the rift system (Fig. 5, nos 7–13)[18–22].

The Oldowan sites are clustered in two fault-bounded blocks of sediment constituting the Middle Bodo Beds[6]. The northern block contains fauna which indicate an age of 1.3–1.5 Myr. The stratigraphical relationships of the archaeological occurrences in the northern and southern blocks at Bodo remain to be worked out in detail. The most informative site, BOD-A3, is situated in the south-east sector, in the Ounda Bodo catchment. A total of 389 stone artefacts and numerous fragmentary faunal remains were found in relatively fresh condition scattered over a steep-sided outcrop of fine-grained fluvial deposits. Surface artefacts include several flake scraper forms ($n = 10$) as well as modified and utilized flakes and cobbles including hammerstones ($n = 8$). The major proportion of the assemblage ($n = 371$) is cores, unmodified flakes and flaking debitage. Another 45 stone specimens were recovered *in situ* from a 10 m^2 excavation. Fine-grained basalt was the preferred raw material but artefacts were also made on glassy or aphyric rhyolite, welded ignimbrite and chert. Most faunal specimens are highly fragmentary and

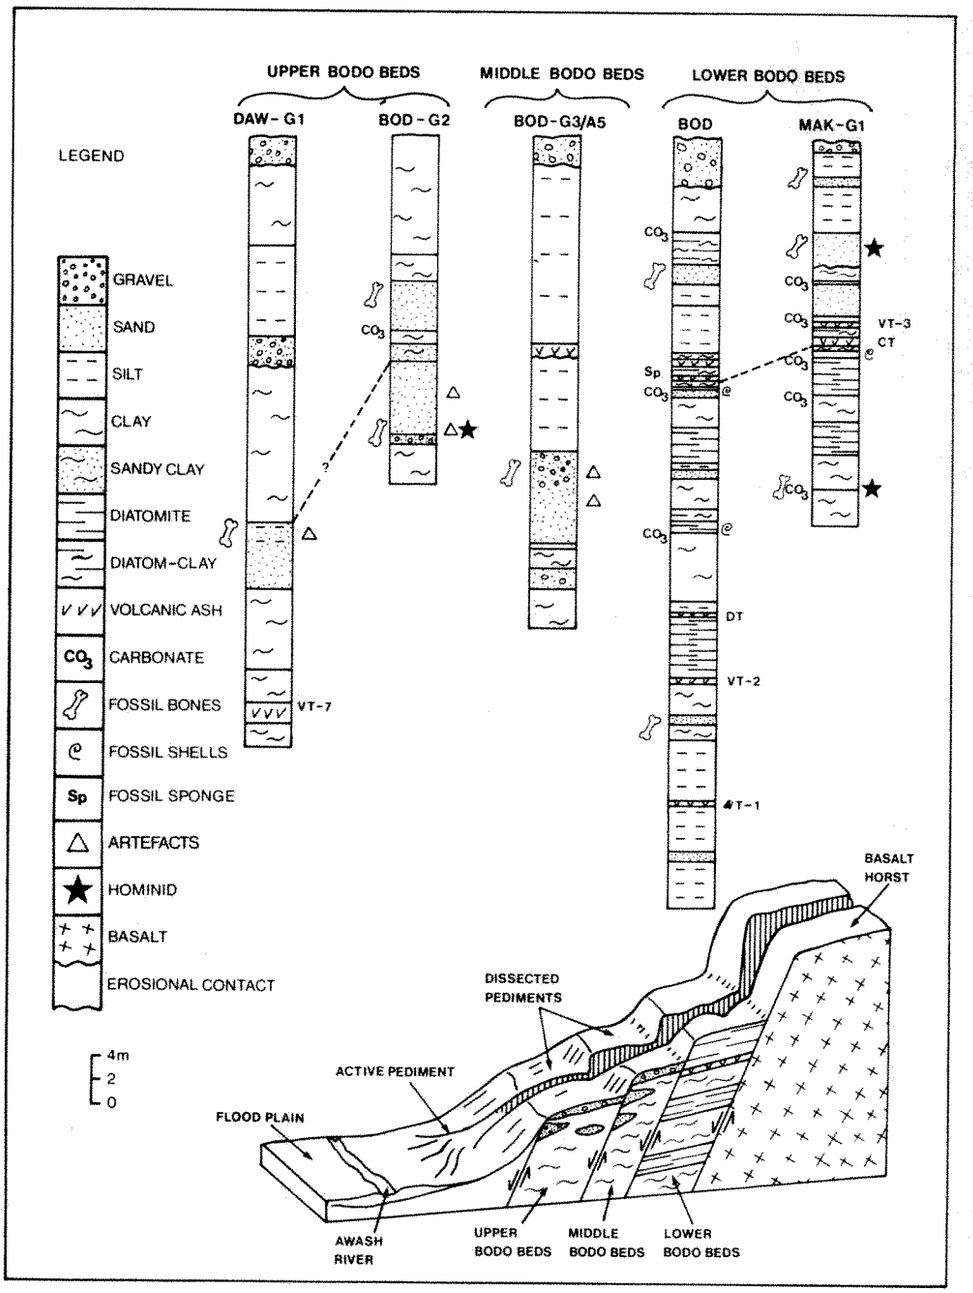

Fig. 2 Representative geological columns showing the three main stratigraphical elements present at Bodo. Also shown are the stratigraphical positions of artefacts and the three fossil hominids found in 1981. The Pliocene section at Bodo is a composite of three separate measured sections (DAW-GO1, BOD-G1 and BOD-G13, see Fig. 1) that were correlated in the field using the Cindery Tuff (CT) or Doublet Tuff (DT) as stratigraphical markers. An idealized cross-section is presented which illustrates the general geomorphic, stratigraphical and structural relationships between the main stratigraphical elements in this area.

the long bone fragments display longitudinal and spiral fracture. No cutmarks were observed. The fresh condition, lack of size sorting, lack of preferred orientation and sedimentary matrix of the specimens indicate a low-energy environment of silty overbank deposition suggesting an occurrence in minimally disturbed context.

Several similar archaeological occurrences were found nearby in overbank silty deposits. Close to one of these, designated BOD-A4, clay samples were collected from a cone-shaped, reddish area. Magneto-thermal analyses by M. Barbetti at the University of Sydney Radiocarbon Laboratory showed that the BOD-A4 clay samples had been baked. Such baked clay concentrations occur in sediments ranging in age from Pliocene to Middle Pleistocene in the Middle Awash. Stone artefacts and fractured bone occurred adjacent to some of these concentrations in the Pleistocene sediments while others again had nothing associated. Two Middle Pleistocene occurrences were sectioned and found to consist of a cone-shaped mass of burnt clay with a shallow concave base. Channels in some of these burnt concentrations are evidence of insect activity, probably termites. These features have the appearance of the burnt earth that is built up round the bases of old trees and tree stumps that have burned and are commonly to be seen in the tropics today. While it seems likely that many of these occurrences resulted from 'natural' fires, the observation made by one of us (J.D.C.) in central India early in 1982 of the way in which tree stumps were set alight intentionally by farmers, in order to have fire always available when they were working in areas distant from the homesteads, makes it possible, so great is the attraction and significance of fire for the human race, that early hominids might similarly have used and preserved fire in such a manner.

In view of the controversy surrounding the controlled use of fire by early hominids[23,24] and due to the fact that these localized, discoloured areas are a widespread phenomenon in the Middle Awash, a systematic study of these features to determine more precisely the nature of each occurrence, temperature ranges, palaeomagnetic field strengths, the agencies that caused the baking and the extent to which artefacts and bone may be significantly associated should be given high priority in the future.

Acheulian and developed Oldowan

The two occurrences that can be assigned to an earlier stage of the Acheulian Industrial Complex—from Maka and

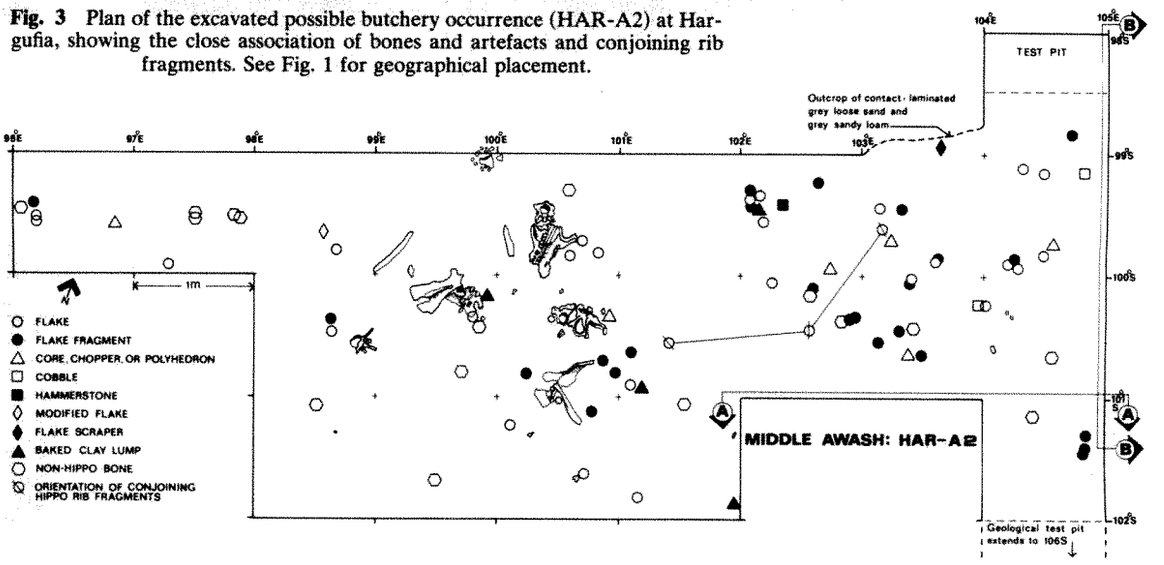

Fig. 3 Plan of the excavated possible butchery occurrence (HAR-A2) at Hargufia, showing the close association of bones and artefacts and conjoining rib fragments. See Fig. 1 for geographical placement.

Dakanihyalo—are made from lavas and comprise thick-butted and sometimes triagular-sectioned bifaces, core-choppers and flakes technologically and typologically analogous to Lower Acheulian assemblages from East Africa[22,25]. The fauna associated with the Dakanihyalo assemblage as well as the technological and typological attributes of the artefacts suggest, therefore, that the Dakanihyalo Member of the Wehaietu Formation may antedate, rather than postdate, the Bodo and Meadura Members[7,8].

On the east side of the Awash, deposits (Upper Bodo Beds[6]; Wehaietu Formation[7]) that outcrop closest to the river consist mostly of sterile brown clays and silts but interbedded strata in the Bodo, Dawaitoli, Hargufia and Meadura catchments are particularly rich in artefact assemblages that we ascribe to the Upper Acheulian and developed Oldowan industrial complexes. Those occurrences least disturbed by fluvio-lacustrine resorting or other agencies are found within massive silts and clayey fine sands which often merge laterally into coarse channel sands and gravels. Where stone artefacts are found within channel sands they may be imbricated but have not necessarily been moved very far.

Four test excavations were carried out in 1981. Assemblages are mostly of two kinds—either (1) large concentrations of Acheulian handaxes and cleavers with flaking waste but a significant paucity of light-duty artefacts and fauna (for example, BOD-A2) or (2) developed Oldowan-type assemblages of flakes (some retouched), core/choppers, and so on; the latter are associated with much broken bone material. In the Acheulian assemblages cleavers predominate over handaxes and, though these were retouched at the sites where they were used, the primary flakes from which they were made were obtained elsewhere and carried into the activity areas. These flakes appear to have been struck from 'giant polyhedron' cores of basalt that occur as erratics in the Upper Bodo Beds[6]; Wehaietu Formation[7]. Twelve of these cores were studied; each weighed more than 100 kg, averaged ~30 cm on a side and showed the scars

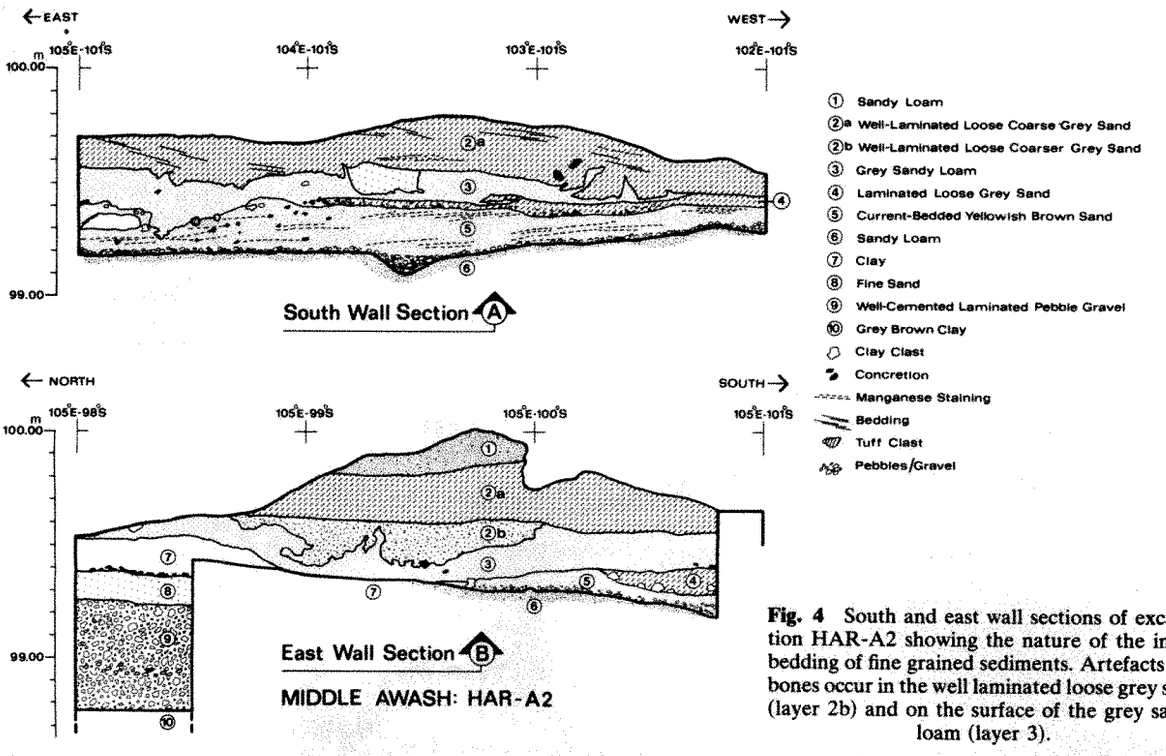

Fig. 4 South and east wall sections of excavation HAR-A2 showing the nature of the interbedding of fine grained sediments. Artefacts and bones occur in the well laminated loose grey sand (layer 2b) and on the surface of the grey sandy loam (layer 3).

of on average from four to six large flakes that had been struck from them.

Assemblages of Developed Oldowan light duty artefacts associated with bone are of two kinds. First, occurrences similar to those from the excavated site BOD-A1 which contains a small concentration (4 × 3 m) of broken bone representing possible food waste and fresh flakes, all in a fine silty sand. The bone represents fragmentary remains of large, medium and small bovids, a canid, crocodile and catfish. Associated artefacts (n = 136) consist of small primary flakes having an irregular planform and mostly plain striking platforms. Also present was a single, radially-flaked biconical core which is likely to have been the source of most of the flakes. Second, occurrences consisting of the remains of a single large animal, usually a hippopotamus, with associated artefacts. These have been considered to be butchery sites[8]. Most of those studied in 1981 were found to be in channel sands and gravels and to represent fortuitous secondary context accumulations of artefacts and bone brought together by fluvial agencies. However, one potential hippo butchery site was partially excavated at Hargufia (HAR-A2, Fig. 3). While the artefacts (n = 76) and bone (n = 38) are in fresh and unweathered condition and occur within an area of 25 m^2, they are also in secondary context. The crossbedded and poorly sorted, laminated, grey sand in which they occur (layer 2b; Fig. 4) indicates a relatively low energy current. Hippo bones (including a complete cranium, vertebrae, ribs, an innominate and scapula) show a narrow range of alignment. Joining fragments of a single rib have been displaced by little more than 1 m (Fig. 3) and both heavy and light elements occur together, evidence suggesting that the assemblage had been minimally disturbed before burial. The artefacts represent a low density occurrence and are made mostly from basalt but also from chert, rhyolite and obsidian (Fig. 5, nos 1–6). Shaped tools comprise convex side-scrapers (n = 2), polyhedron (n = 1) and sub-spheroid (n = 1), and there are three modified flake fragments. The remainder consist of unmodified small flakes (n = 26), cores (n = 5, including two discoid), flake fragments and chunks. Also associated are four lumps of burnt clay. The tight spatial relationship of bones and artefacts makes it likely that this is a butchery site and kit used by middle Pleistocene hominids.

While it is the light duty flake component that has come to be more generally associated with butchery, it should be noted that a single plotted but unexcavated surface scatter (HAR-A4) of 55 handaxes and five cleavers with hippopotamus bone ~1 km north of HAR-A2 may support Jones[26] contention that Acheulian bifaces were primarily butchery tools. The absolutely fresh and unabraded condition of the artefacts and bone fragments at HAR-A4 suggests that a large part of a single animal may still remain buried while the uniformity in biface symmetry, size and shape and the absence of trimming flakes suggest that these tools were made and used on a single occasion only.

Larger concentrations of bifaces do exist in the Afar but they appear to be rare and this pattern of small, concentrated occurrences of bifaces and light duty artefacts made for one occasion only is that which we have found to predominate in the area. Moreover, the Acheulian (bifaces) and developed Oldowan (flake/core-chopper) components are usually not found together in the same assemblage, the possibility is suggested that each may represent a different set of cultural activities. Unlike, therefore, the large concentrations of the Ethiopian and south-east plateaux sites where both components occur together[27,28], these sites in the Afar depression may provide a better opportunity for identifying what the activities may have been.

Fossil hominid discoveries

The 1981 survey resulted in the recovery of the posterio–inferior corner of a large left hominid parietal (BOD-VP-1/1, found by T.D.W.) ~400 m south of the original Bodo hominid discovery[4] and from the same Middle Pleistocene stratum. The new specimen preserves a part of the vault not seen on the original Bodo find. It represents a second, geologically contemporary adult

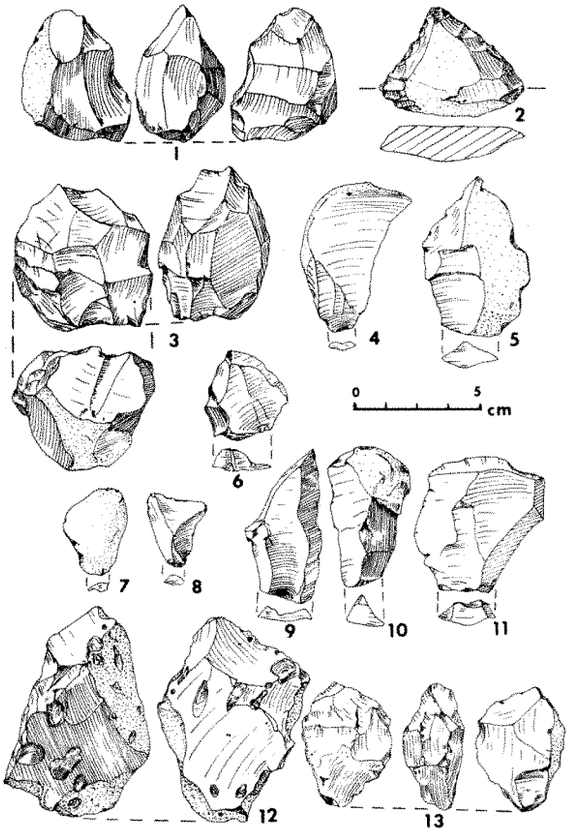

Fig. 5 Nos 1–6: artefacts from the 'Upper Bodo Beds' in the Hargufia drainage. *In situ* in HAR-A2 excavation; possible hippo butchery occurrence. All in fresh condition. 1, Angle core (side chopper): basalt (A2-19). 2, *Dejete* scraper on cortex flake: rhyolite (A2-59). 3, Multi-platformed core (three platforms): basalt (A2-4). 4, Cortex-backed knife on irregular end-struck flake: basalt (A2-20). 5, Irregular end-struck flake with marginal notching: basalt (A2-2). 6, Short sub-triangular flake: basalt (A2-10). Nos 7–13: artefacts from the 'Middle Bodo Beds' in the Bodo drainage. Oldowan Industry artefacts *in situ* from BOD-A3 excavation. All in fresh condition. 7, Irregular end-struck cortex flake: rhyolite. (A3-905). 8, Irregular end-struck flake: basalt (A3-904). 9, Irregular end-struck flake: basalt (A3-907). 10, Irregular end-struck flake (core trimming flake): basalt (A3-880). 11, Irregular end-struck flake: basalt (A3-911). 12, Single platform core (unifacial side and end chopper): vesicular basalt (A3-899). 13, Angle core (bifacial side chopper): basalt (A3-908).

individual of the same taxon. The parietal is robust, measuring 20.8 mm across asterion, the greatest such dimension recorded for a hominid. The specimen features a strong supramastoid crest extension, a massive angular torus and a wide temporal overlap[29].

An adolescent left proximal femur of a Pliocene hominid (MAK-VP-1/1) was found at Maka (by T.D.W.) only 7 m above the projected CT horizon in a limonite-stained gravelly sand that yields a diverse and abundant fauna. An erosional disconformity separates the hominid from the radiometrically dated CT horizon. However, the presence of primitive *Notochoerus euilus*, *Nyanzachoerus kanamensis*, *Elephas recki brumpti*, primitive *Theropithecus*, *Ugandax* sp., *Predamalis deturi* and *Ceratotherium praecox* demonstrates that the Maka femoral fragment is at least as old as the Sidi Hakoma member of the Hadar Formation immediately to the north and the Laetolil Beds in Tanzania. The age of the former deposits remains unresolved[30–32] while the latter are well dated to ~3.7 Myr (ref. 33). We therefore assign an age of 3.5–4.0 Myr to the Maka femoral fragment.

Approximately 700 m north-east of the Maka femur find a second Pliocene hominid fossil was recovered, 11 m below the

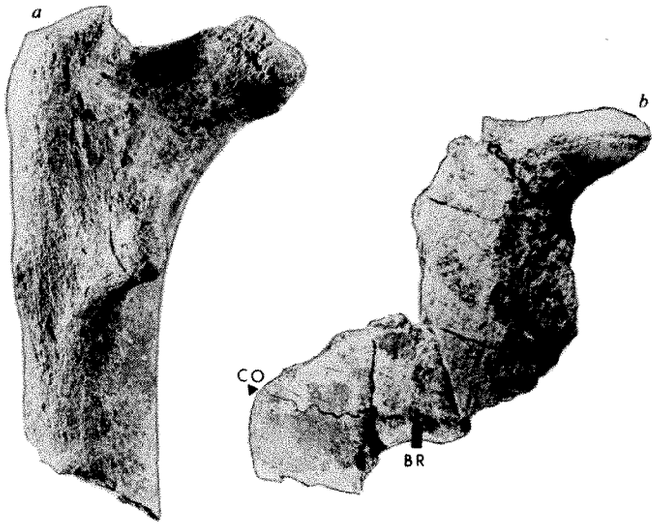

Fig. 6 Pliocene hominids from the Middle Awash, 1981. *a*, Proximal femur from Maka (MAK-VP-1/1). *b*, Frontal from Belohdelie (BEL-VP-1/1). CO indicates the coronal suture and BR indicates bregma. See text for details. See Figs 1 and 2 for geographical and stratigraphical placement. ×, 60%.

CT in the Belohdelie drainage. The specimen (BEL-VP-1/1, found by L. Krishtalka) consisted of seven vault fragments eroding from Pliocene sediments. Three of the fragments join to comprise much of an adult hominid frontal. The geological correlation for the two Pliocene hominids with respect to the CT is firm. Matrix on the fossils indicates that these surface finds eroded from the deposits on which they rested. Limited stratigraphical exposure at both localities argues against the fossils' being derived from younger sediments so that these cranial fossils are securely placed at >4.0 Myr, an age consistent with associated fauna.

The new Pliocene fossils from the Middle Awash (Fig. 6) are important because of their antiquity and because they represent functionally critical parts of the hominid skeleton. The Pliocene femur fragment represents an individual whose greater and lesser trochanters had fused. The femoral head was beginning to fuse but is now lost leaving the subepiphyseal surface partially intact. The specimen was virtually adult in size and is intermediate between the smallest (A.L. 288-1, 'Lucy') and the largest (A.L. 333-3) Hadar femora. It agrees in detail with the anatomy seen in *A. afarensis*[34]. A suite of external morphological features diagnostic of habitual bipedality is evident on the Maka specimen. These characters include the position of the lesser trochanter, the length of the neck, the morphology of the obturator insertion, the shape of the superior notch, the height of the greater trochanter and the clear obturator externus groove. The specimen is susceptible to a variety of X-ray techniques, including xeradiography and computerized tomography. The presence of thickened cortex through the ventral portion of the neck and the strong calcar also indicate habitual bipedality.

The Belohdelie specimen is stratigraphically older than the Maka femur. This fossil is of outstanding importance because it fills the last unknown area of adult cranial anatomy in the earliest Pliocene hominids. The only other hominid vault remains approaching this age belong to *A. afarensis*[35]. The Belohdelie frontal resembles that of the Laetoli child (L.H.-21)[35] and conforms well to predictions made by a composite cranial reconstruction of an adult Hadar male[36]. The new fossil is thick, measuring 8.4 at 10.0 mm anterior to bregma. Frontal length is diminutive and the overall size of the bone is equivalent to that of an adult chimpanzee. The small size and apelike morphology of the supraorbital corner combine to indicate a primitive status for the fossil. The lack of marked postorbital constriction or strong temporal line convergence is different from the robust *Australopithecus* condition. The small vault size and long, low, flat frontal squama set the specimen apart from *Homo*. Vault thickness and lack of a supratoral sulcus are traits not seen in African pongids. The morphology of BEL-VP-1/1 suggests that the fossil is best considered to belong to *Australopithecus*, a hominid genus. The specimen constitutes a significant addition to our knowledge of Pliocene hominid form and emphasizes the primitive nature of early hominid cranial architecture.

We anticipate that further fieldwork in this area will yield additional significant results.

We thank the following for assistance: The Government of Socialist Ethiopia, including the Ministry of Culture and Sports Affairs, the Ministry of Mines and Energy, the Game Commission; Addis Ababa University; the Centre for Research and Conservation of the Cultural Heritage and the National Museum of Ethiopia. Funding was provided by the NSF (BNS 80-19868) and the L. S. B. Leakey Foundation. Photographic assistance was granted by the National Geographic Society. D. C. Johanson provided critical field equipment and support. The following individuals provided valuable comments and data: D. A. Adamson, J. Aronson, M. Barbetti, M. Beden, E. Delson, F. Gasse, C. Hall, W. H. Kimbel, C. O. Lovejoy, E. Meikle, E. Vrba, J. Westgate and D. York. Very special thanks go to all the 1981 expedition members for their participation and for making this fieldwork such a success: especially to Dr L. Krishtalka, R. J. Blumenschine, B. C. Clark, T. Kaleu, C. E. Sussman, M. Tesfaye, Tafesse G. Egziabher and C. Yirgu. Their work is gratefully acknowledged. The assistance of the Afar people of Gewane and Aramis is gratefully appreciated.

Origin and evolution of the Mediterranean vegetation and climate in Europe

J.-P. Suc

Laboratoire de Palynologie, Institut des Sciences de l'Evolution (LA 327 CNRS), Université des Sciences et Techniques du Languedoc, 34060 Montpellier Cedex, France

Palynology provides information about Pliocene and early Pleistocene vegetation and climate evolution in the north-west Mediterranean area in relation to high northern latitude climatic trends. An important change occurred approximately 3.2 Myr ago with the appearance of the Mediterranean climatic rhythm (summer drought) causing the individualization of the modern Mediterranean floral elements. Quaternary-type mediterranean climatic fluctuations started approximately 2.3 Myr ago (early Glacial) causing the Mediterranean-type of vegetational organization.

MEDITERRANEAN climatic conditions are today distinctive and consist of a temperate climate characterized by dry summers with rainfall concentrated during the other seasons and low temperatures during winter. Floral assemblages and the vegetational organization are therefore very typical. To understand present day ecosystems it is essential to establish when and how the summer drought first occurred.

A model based on fossil macrofloras was proposed for California[1] (a region now displaying the same climatic and vegetational features as the Mediterranean area[2,3]) but there is at present no equivalent for the Mediterranean area where recent advances in palaeoclimatic knowledge are based mainly on studies of marine deposits, particularly from DSDP site 132, according to foraminifera[4,5], isotopic measurements[6] and clay minerals[7]. This research has yielded information about water temperatures and about rainfall rhythm. Until recently, reliable palaeoenvironmental floristic records based on pollen grains[8–10] and macroremains[11,12] were scarce.

Our own palynological research has been concentrated in the Gulf of Lion (off-shore sequences and terrestrial sections in Languedoc, Roussillon and Catalunya). New data have been obtained from off-shore sections in the Adriatic Sea and from lacustrine deposits in southern Italy (Fig. 1). Long palynological sequences covering the whole Pliocene and early Pleistocene were yielded by off-shore sections (Autan 1[13] and Garraf 1[14] in the Gulf of Lion and the Adriatic Sea, J. Cravatte and J.-P.S., unpublished data) in which the biostratigraphic control is based on planktonic foraminifera and nannoplankton. The foraminiferal zonation adopted in this article has been determined in the Gulf of Lion[15] with reference to the DSDP site 132 chronology[16]: *Globorotalia margaritae s.l.* zone, the top of which is marked by *G. puncticulata* decreasing or absent just above the *G. margaritae* extinction (from approximately 5.4 to 3.2 Myr ago); *G. crassaformis* zone, the top of which is marked by the first appearance of *G. inflata* (3.2–2.2 Myr ago); *G. inflata* zone, the top of which is marked by the first appearance of *Hyalinea balthica* (2.2–1.8 Myr ago). Short terrestrial sections (marine coastal or lacustrine deposits) have been investigated[14,17–19] and their chronological placement obtained from mammal biochronology[20] and sometimes from K–Ar (ref. 21) and palaeomagnetic measurements (refs 22, 23 and N. A. Mörner, personal communication).

Appearance of Mediterranean climate

During the Lower Pliocene (Tabianian stage, approximately represented by the *G. margaritae s.l.* zone[15]), the north-west Mediterranean area had a dense forest vegetation composed of: (1) a coastal association in which Taxodiaceae predominated (*Taxodium*-type especially), *Myrica*, *Symplocos*, *Nyssa*; and (2) just behind it, assemblages with *Engelhardtia*, *Carya*, *Rhoiptelea*, *Hamamelis*, *Embolanthera* growing in less damp biotopes.

Moist climatic conditions (with rainy summers) prevailed during this time (P I pollen zone[24]; Fig. 2*A*) and climatic fluctuations are revealed by pollen assemblages of the subzone P Ib, denoting less humid conditions. Such assemblages can be compared with the present evergreen sclerophyllous broad-leaved forest in China[25].

A great change occurred approximately 3.2 Myr ago that modified the composition and structure of the forests. The coastal forest swiftly grew thinner and disappeared. Components of the sclerophyllous forest also changed and *Quercus* species and *Alnus* (in damp biotopes) became predominant. Furthermore, xerophytic taxa (those of the present-day Mediterranean) rose by degrees to higher frequencies (*Phillyrea*, *Olea*, *Cistus*, *Quercus ilex*-type, *Pistacia*). During the beginning of this phase all species of Taxodiaceae disappeared from Languedoc-Roussillon[26].

The P I–P II boundary (Fig. 2*A*) is a climatic event, rather than related to the local Piacenzian transgressive phase, not only because of the disappearance of the coastal forest which does not occur everywhere (in Catalunya, it diminished but did not disappear at that time), but also because of the change in the structure and the composition of the sclerophyllous forest. Moreover, this boundary precedes (Rhône Valley) or follows (Catalunya) the transgressive movement. During the same time, some subtropical planktonic foraminifera disappeared from the Mediterranean Sea (*G. margaritae*, *G. puncticulata* and *Sphaeroidinellopsis*[4]).

Vegetational assemblages were certainly complex. Although a latitudinal and altitudinal zonation existed, a mosaic distribution most likely existed in relation to the relief, and different types of soils: for instance, *Cedrus* pollen grains are only abundant in western Languedoc and less so in Catalunya deposits which are located near south-facing metamorphic and granitic mountains; *Abies*, *Picea* and *Fagus* pollen grains are numerous at the opening of the Rhône Valley.

At the beginning of the P II pollen zone (Fig. 2*A*), all taxa requiring a year-long degree of moisture decreased or disappeared while xerophytic ones increased (frequencies and absolute counts[24]). *Phillyrea*, *Olea*, *Cistus*, *Quercus ilex*, *Pistacia*, which ultimately came to characterize the Mediterranean flora, were already abundant and appear to have been the most resistant to the new climatic conditions and the most adaptative but did not yet form specialized associations. Today, similar assemblages are developed in the eastern Mediterranean (Pontic) area where *Phillyrea media*, *Quercus ilex*, *Rhamnus alaternus* grow under humid conditions (maximum rainfall in summer) and are associated with deciduous forest (*Quercus*, *Pterocarya*, *Fagus orientalis*)[27]. *Pistacia*, *Phillyrea*, *Cistus*, *Olea* and the *Quercus ilex*-group (evergreen species) were present in the north-west Mediterranean area at the base of the Miocene beds (sometimes in high percentages) and mixed with tropical assemblages[28].

Also during P II, sedimentary trends evolved into coarse and red deposits chiefly in Languedoc-Roussillon. The significance

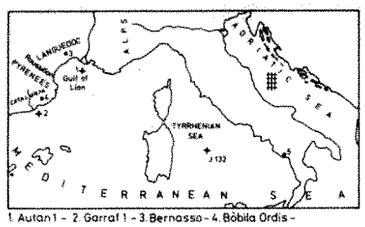

Fig. 1 Location map of the Plio-Pleistocene palynological sequences utilized in this paper. The planktonic foraminifera biostratigraphy of Autan 1 and Garraf 1 wells is referred to the DSDP site 132 chronostratigraphy.

of this has been explained as a shrinking of the forest surface caused by an increase in xericity[29]. The composition of the Ruscinian mammal faunas which mostly correlate with the P II pollen zone is in accordance with the new vegetational and climatic characteristics of that time. For instance, the Muridae, which predominated among rodents, are now living in open forest subtropical biotopes[20].

According to all these recent data, we consider that at the beginning of the Piacenzian stage (approximately 3.2 Myr ago) the climate of the north-west Mediterranean area evolved towards a seasonal rhythm of great contrast and the summer drought became stable approximately 2.8 Myr ago (Fig. 3). This opinion is supported by the changes in vegetation occurring later and hereunder described.

Earliest modern-type climatic fluctuations

In the upper part of the *G. crassaformis* zone which overlaps with the first appearance in the Mediterranean Sea of the planktonic foraminifera *G. inflata* (until then characteristic of northern latitudes)[15], 'steppic' pollen assemblages were on the increase (*Artemisia*, *Ephedra*, other Compositae, Caryophyllaceae, Amaranthaceae–Chenopodiaceae, *Erodium*)[30] compared with low frequencies of arboreal pollen grains (*Pinus* excepted). The P III pollen zone, as defined in the Autan 1 and Garraf 1 sections, has a climatic significance without any relation to the marine regression in the Gulf of Lion which occurred much earlier (Fig. 2*A*)[24]. Moreover, this climatic zone, which lasted about 0.2 Myr (approximately from 2.3 to 2.1 Myr ago[31]), was also registered in the Adriatic series (J. Cravatte and J.-P.S., unpublished data). Pollen spectra clearly demonstrate a reduction of forest cover and the enlargement of 'steppic' vegetational associations denoting drier and probably milder climatic conditions[24] (Fig. 3).

The next pollen zone (P VI–Pl. I) where the Pliocene–Pleistocene boundary occurs was recognized in southern Italy[19] (Camerota) and in the Adriatic sections. Forest associations predominated again but *Quercus*, *Carya*, *Carpinus*, *Ulmus–Zelkova* were then the most abundant taxa along with *Acer*, *Pterocarya*, *Parrotia persica*. Palaeogeographic reconstructions and comparisons between pollen- and macro-floras show an established Mediterranean vegetational zonation (P. Brenac, personal communication) as follows:

(1) The coastal *Olea–Ceratonia* association (accompanied by *Pistacia*, *Phillyrea* and *Myrtus* that is, thermo-Mediterranean).

(2) The *Phillyrea–Quercus ilex* association (accompanied by *Olea*, *Carpinus orientalis* and *Rhamnus*; that is, meso-Mediterranean).

(3) The deciduous *Quercus* forest with *Carpinus* (*C. orientalis* and *C. betulus*), *Carya*, *Ulmus* and *Zelkova* (the supra- or humid-Mediterranean zone).

(4) Mountain forest including *Cedrus*, *Pinus*, *Abies*, *Picea* and *Tsuga*.

This is an altitudinal zonation characterized by increase in moisture and decrease in temperature. The present model of such forests must be sought in Pontic and to a less degree in Caspian areas[27,32]. From a climatic point of view, the P VI–Pl. I phase

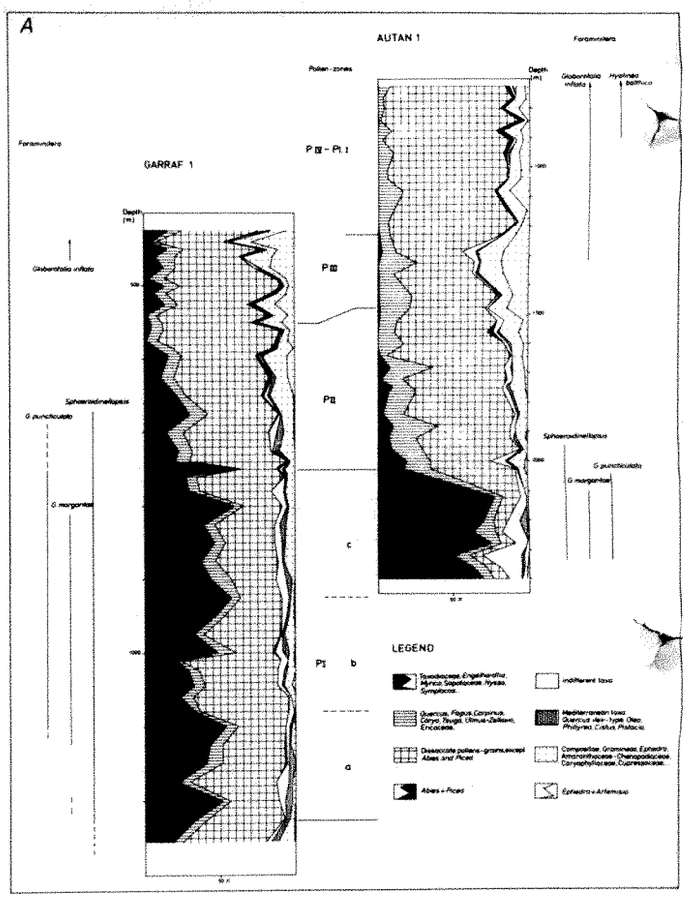

Fig. 2 Synthetic pollen diagrams based on ecological assemblages. *A*, Garraf I 1 and Autan 1 with the planktonic foraminifera first and last appearance data; the pollen zones are founded on the vegetational changes; notice the decrease of taxa requiring a year long degree of moisture (P I–P II boundary) and the increase of 'steppic' elements (P III pollen zone). *B*, Bernasso: two 'steppic' phases are bordering a deciduous forest period (interstadial). *C*, Bòbila Ordis: an interglacial deciduous forest phase.

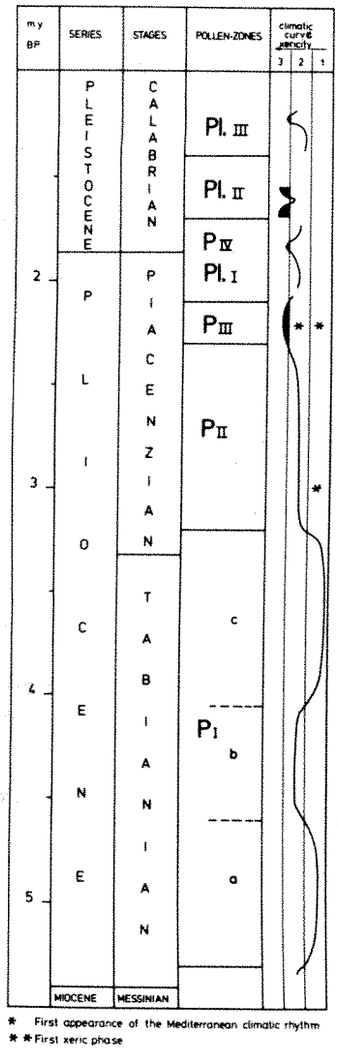

Fig. 3 Climatic evolution in north-west Mediterranean area during the Pliocene and Lower Pleistocene. The Quaternary-type climatic fluctuations began with the oldest 'steppic' phase P III.

indicates a return to moister (rainfall increasing) and warmer conditions[24] (Fig. 3).

With the P III period, the climate started fluctuating as it did in the late Pleistocene. The oldest cycle is constituted by P III and P IV–Pl. I phases, the second one[24] (Fig. 3) includes Pl. II (recognized at Bernasso[18] and in Adriatic sections—Fig. 2*B*; drier and probably cooler than P III) and Pl. III phases (recognized at Bòbila Ordis[33] and Nogaret—Fig. 2*C*; certainly warmer than P IV–Pl. I); the next cycle is incompletely known up till the lowermost oscillation in the Tenaghi Philippon pollen diagram (northern Greece) which is dated at 0.7 Myr ago[34].

These mean early climatic periods can be subdivided into several minor phases (Figs 2*B*, 2*C*, 3). The abrupt transition between two alternating minor phases appears difficult to understand but the possibility of an intermediate climate oscillating over both sides of a threshold should be considered. This is one of the reasons why we do not consider that early 'steppic' phases denote cool conditions but only drier and perhaps milder ones. Another argument is provided by some differences between the oldest and most recent 'steppic' associations as is indicated in the early Pleistocene by the presence of thermophilous elements (*Cistus*, *Phlomis* cf. *fruticosa*, *Erodium*). Thus it would be possible to discriminate between ancient Mediterranean 'steppes' and recent ones by reference to the differentiation now existing between steppes with dry and cool determinism[27]. This supports the idea of dividing the Mediterranean Pleistocene into two distinct climatic periods, the earliest warmer and the latest characterized by important temperature fluctuations[5,35]. On the other hand, the transition between two main successive vegetational (then climatic) phases appears to have been gradual as proved by the different noticeable subdivisions in the P VI–Pl. I pollen zone. In short, the modern type of Mediterranean climatic fluctuations started in the late Pliocene; the periodicity and the amplitude of these successively dry and humid periods increased up to the present.

Conclusions

Chronological relationships between the Mediterranean Plio-Pleistocene climatic fluctuations and those defined in north-west Europe[36,37] can be established. Correlations are based both on independent chronological data and on the correspondence between Mediterranean 'steppic' and tundra-like pollen spectra on the one hand and forest pollen assemblages on the other corresponding respectively to late Glacial and Holocene models[31]. Before the P III pollen zone, relationships between the Mediterranean area and north-west Europe are less obvious than in later periods; nevertheless an equal number of climatically connectable changes is observed in the two areas[31].

The following relationships[31] are thus proposed (Fig. 3):

Pl. III	Waalian	P III	Praetiglian
Pl. II	Eburonian	P II	Reuverian
P VI–Pl. 1	Tiglian	P I	Brunssumian

Therefore, climatic changes which occurred in the Mediterranean area are essentially related to temperature changes in the high northern latitudes[31].

The cooling dated at approximately 3.2 Myr ago was a global event that has been recognized in planktonic foraminifera[4,5,38] and oxygen isotopic curves[6,39,40]. In the Mediterranean area, the same trend in isotopic curve could indicate "an increased evaporation relative to precipitation"[6] which would be in accordance with information deduced from pollen records. The P I–P II boundary climatic event is probably related to this cooling caused by the beginning of the permanent glaciation in the Arctic area which in turn is related to the Gulf Stream intensification due to gradual uplift of the Panama isthmus[41]. This climatic event was preceded by the less humid P Ib phase in the Mediterranean area (that is, Brunssumian B in north-west Europe[31]) as also indicated by planktonic foraminifera data[5]. The climatic trends as revealed by palynological records in the Mediterranean area are quite similar to those indicated by data obtained from planktonic foraminifera and isotopic studies. Furthermore, palynology yields additional information about changes in moisture. The two main climatic changes occurred at around 3.2 and 2.3 Myr ago, the greater importance of the later event being generally accepted today (L. D. Keigwin, Jr. personal communication). Moreover, according to these different methods there is wide agreement that the Pliocene–Pleistocene boundary is not characterized by climatic cooling[4,5,24,31].

The pollen analysis allows distinction in the Mediterranean area between interglacial and interstadial forest phases. For instance, the forest phase in the Bòbila Ordis pollen diagram corresponds to an interglacial period shown by high frequencies of deciduous oaks (that is, the interglacial forest climax in the Mediterranean area), the presence of the two hornbeam species (*Carpinus orientalis* and *C. betulus*) and *Parrotia persica* as opposed to low percentages of Mediterranean 'steppic' elements even in the upper part of the pollen diagram (Fig. 2*C*); moreover, the relative high representation of Mediterranean taxa and the succession in vegetational features are characteristic. In contrast, very low frequencies of deciduous oaks and only one hornbeam species (*C. orientalis*) characterize the interstadial forest phase in Bernasso pollen diagram while Mediterranean 'steppic' components reach high values (Fig. 2*B*).

The beginning of the evolution of the Mediterranean-type climate has been characterized more by fluctuations in moisture (especially in rainfall rhythm) than in temperature. From the early Pliocene onwards, the climate was already fluctuating but the period and the amplitude increased during the Pleistocene.

Two very important steps are located at approximately 3.2 Myr ago (progressive establishment of the Mediterranean rhythm with dry summers; individualization of the modern Mediterranean floral elements) and 2.3 Myr ago (the oldest xeric phase; starting of the Quaternary-type oscillations; oldest signs of a Mediterranean-type vegetational organization). The previous flora was decimated and the vegetation thoroughly modified because of the intensity and rapidity of the climatic changes and, finally, human activity had a considerable effect.

We thank M. Van Campo, Ph. Guinet, J. Michaux and J.-L. Vernet for discussing the results, J. Holmes for reading the manuscript and Dr L. D. Keigwin Jr and R. C. Thunell for helpful comments. This work was supported by CNRS and the Compagnie Française des Pétroles.

A mouse major histocompatibility antigen (H–2) gene, encoding a novel H–2L^d molecule lacking its intracytoplasmic domain, has been constructed and introduced into mouse L-cells. The novel H–2 molecule is found on the surface of the transfected cells at the same level as L-cells transfected with the native H–2L^d *gene. Allo- and influenza-specific cytotoxic T lymphocytes can recognize the truncated* H–2 *gene product nearly as efficiently as the normal* H–2L^d *gene product. However, vesicular stomatitis virus-specific cytotoxic T lymphocytes recognize the truncated H–2L^d molecule less efficiently than the complete H–2L^d product. The rate of capping of the truncated H–2L^d molecule was investigated and found to be the same as that of the complete* H–2L^d *gene product.*

THE major histocompatibility complex (MHC) of the mouse encodes a variety of cell-surface glycoproteins involved in the immune response[1,2]. H-2K, H-2D and H-2L are the three murine major histocompatibility antigens that have been defined by classical genetic and serologic critera. These transplantation antigens are members of a family of proteins referred to as class I antigens. The class I molecules are glycoproteins that consist of two subunits, β_2-microglobulin and H-2. The 12,000 molecular weight β_2-microglobulin chain is found only on the extracellular part of the protein. The H-2 subunit is about 345 amino acids long and is encoded by a gene comprised of 8 exons[3–5] (Fig. 1). The first 280 residues are on the extracellular side of the cell membrane, 40 residues are thought to be imbedded in the cell membrane and the final 25 residues are inside the cell. The role of these intracellular residues of the H-2 molecule is the subject of this article.

Class I molecules serve as targets for T-cell mediated cytolysis in allogeneic immune responses, such as *in vivo* graft rejection and destruction of allogeneic cells by cytotoxic T lymphocytes (CTLs) *in vitro*. However, the physiological role of transplantation antigens might be to serve as a restriction element in T-cell lysis of virus-infected cells. That is, virus infection of mice generates CTLs whose receptor(s) must interact with the foreign viral antigens and a class I molecule in order to lyse the virus-infected cell[6,7].

Genomic clones encoding H–2L^d and H–2D^d can be introduced into thymidine-kinase deficient mouse L-cells by co-transformation with the herpes thymidine kinase gene[8,9]. The gene products are functionally expressed and can mediate immunologically specific cellular interactions[10,11]. Recently, we have constructed *H–2D^d/H–2L^d* hybrid genes expressing the N and C_1 domains of one molecule and the C_2, M and cytoplasmic domains of the other[12]. The restricting elements for allo- and antiviral CTLs were mapped to the N and/or C_1 domains[13,14]. This approach allows us to begin to define the portions of these molecules important for CTL recognition.

In the present studies, we sought to determine whether the cytoplasmic portion of the H–2 molecule has a role in the process by which T cells lyse their targets. A variety of functions can be postulated for the intracytoplasmic portion of the H–2 molecule. To test these models, we constructed an *H–2L^d* gene in which the cytoplasmic domains have been deleted. H–2 anti-

0028-0836/84/050432—05$01.00

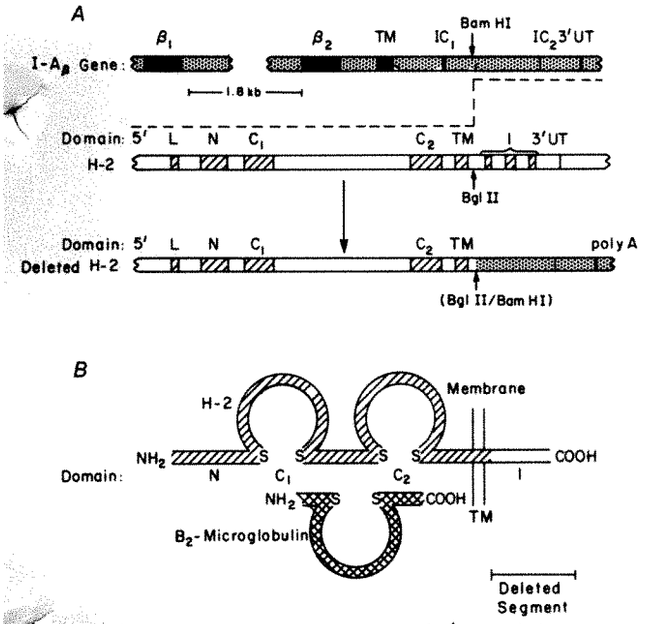

Fig. 1 Construction of the truncated *H-2L*^{d} gene (*A*) and the predicted structure of the deleted H-2 antigen (*B*). The truncated *H-2L*^{d} gene was made from restriction enzyme fragments using standard recombinant DNA technology[32]. A fragment encoding a deleted gene was isolated after a partial digestion of pL^d-4 plasmid DNA with *Bgl*II. A 2.5-kb fragment encoding the last cytoplasmic domain of the murine *I-Aβ* gene cloned into the *Bam*HI site of pBR322 was provided by Dr E. Choi. Partial digestion of this plasmid DNA with *Bam*HI yielded a single fragment containing the 2.5 kb *Bam*HI fragment and the pBR322 sequence. The *Bgl*II fragment encoding the deleted *H-2L*^{d} gene was ligated to the pBR322-I-Aβ fragment, and used to transform *Escherichia coli* strain LE322[33]. The *Bgl*II and *Bam*HI sites destroyed by this procedure are indicated as (*Bgl*II/*Bam*HI) in the deleted gene (*A*). Colonies were screened for the insert having the correct orientation by a 'mini-DNA' preparation followed by restriction enzyme digestion and agarose gel electrophoresis[34]. The resulting plasmid was extensively mapped by restriction-endonuclease cleavage to confirm the reconstruction and that no other rearrangements of the coding regions had occurred. Black areas represent the region coding for the *I-Aβ* gene[16]. Hatched areas represent the regions coding for the *H-2L*^{d} gene[4,5]. Stippled areas represent the intervening sequences and 3' untranslated region of the *I-Aβ* gene. β_1, β_2, TM, IC_1, IC_2, L, N, C_1 and C_2 represent the coding domains of the *I-Aβ* and *H-2L*^{d} genes. The portion of the H-2 molecule that should be deleted by this procedure is indicated in the lower panel.

gens, like other cell-surface molecules, 'cap'. Several models to explain the formation of these caps have been proposed[15]. We have compared the capping of the native and deleted H-2 molecules in order to understand the role of the intracytoplasmic region of the molecule in the capping process.

H-2 molecules with cytoplasmic part deleted

A variety of approaches are available for removing the segment of a gene encoding the COOH end of the protein. For example, Rose and his collaborators have deleted the 3' end of a cloned cDNA of the vesicular stomatitis virus (VSV) G protein by exonuclease digestion (J. Rose, personal communication). The one constraint imposed on restructuring the gene at the 3' end appears to be that a poly (A) addition site must be encoded at the 3' end of the gene. The approach we have taken involves replacement of the exons that encode the intracytoplasmic portion of the H-2 molecule with the portion of the *I-Aβ*^{d} gene that encodes three amino acids and a poly (A) addition site. One advantage of this approach is that the mRNA from the mutant gene is significantly different from the original H-2 gene in that it hybridizes to *I-Aβ* probe.

Detailed structural analysis of the *H-2L*^{d} gene including the determination of the complete DNA sequence, revealed a restriction nuclease site in the intron between the membrane and first cytoplasmic domain[4,5]. Specifically, four *Bgl*II sites are present in the plasmid pL^4-4 (not shown in Fig. 1). Two *Bgl*II sites are located 5' to the promoter region. One *Bgl*II site is located in the C_2 domain and one in the intervening sequence between the membrane and first cytoplasmic domain. Plasmid pL^d-4 DNA was partially digested with *Bgl*II and a fragment was isolated encoding the H-2L^d molecule without the cytoplasmic portion. Recently, the nucleotide sequence of the coding portions of the mouse *I-Aβ* gene has been determined[16]. A 2.5-kilobase (kb) *Bam*HI fragment from the 3' end of the *I-Aβ*^{k} gene encodes a 3' acceptor site, three amino acids, a terminator, a 3'-untranslated region and a poly(A) addition site (Fig. 1*A*). The *Bgl*II fragment encoding the H-2L^d molecule, without the cytoplasmic portion, was ligated to the 2.5 kb *Bam*HI fragment. This construction resulted in an *H-2L*^{d} gene in which the H-2 cytoplasmic domains were deleted (Fig. 1).

Figure 2 shows the amino acid sequence of the transmembrane region and the 25 amino acids comprising the cytoplasmic domain of the native H-2L^d protein. We expected the constructed *H-2L*^{d} gene to encode an H-2L^d molecule with the same transmembrane region as the native H-2L^d molecule, but lacking its cytoplasmic portion. The IC_1, IC_2 and IC_3 encoded portions of the native H-2L^d molecule should be substituted by three amino acids encoded by the cytoplasmic domain from the *I-Aβ*^{k} gene (Fig. 2).

Table 1 H-2L^d antigens on the surface of L-cells containing native and deleted *H-2L*^{d} genes

Cell	*H-2L*^{d} gene	^{125}I-Protein A bound
L cell	—	700
T1.1.1	Native	25,620
T123.8	Native	14,620
D3.8	Deleted	24,642
D3.4	Deleted	19,337

Cloned *H-2* genes encoding either the native or deleted *H-2L*^{d} gene were introduced into thymidine kinase deficient mouse L-cells (DAP-3) by DNA-mediated gene transfer using the herpes simplex thymidine kinase gene as a selectable marker as described previously[4,8]. The amount of H-2L^d expressed on the cell surface was measured by radioimmunoassay[8,12]. 2×10^5 cells were incubated in 50 μl of a 1:1 dilution of a monoclonal H-2L^d antibody (28.8.14) for 2 h at 4 °C. The cells were extensively washed, ^{125}I-labelled Protein A was added, and the cells were incubated for an additional 2 h at 4 °C. After extensive washing the amount of ^{125}I bound to the cells was measured. Each value represents the mean of triplicate samples with a standard deviation of less than 3% of the mean. Although the relative amounts of H-2L^d on the surface varied somewhat from experiment to experiment, the amount of H-2L^d on the surface of T1.1.1 was always very similar to the amount on the surface of the D3.8 cells, while the T123.8 and D3.4 cells had about 50% and 80% respectively of the H-2L^d found on the surface of T1.1.1.

Deleted *H-2* gene products in transformants

To establish whether the truncated gene is expressed when reintroduced into mouse cells, DNA from either the truncated or the complete *H-2L*^{d} gene together with the herpes viral thymidine kinase gene, was used to co-transform thymidine kinase negative mouse L-cells as previously described[17,18]. Transformants were selected in hypoxanthine–aminopterin–thymidine medium and screened with monoclonal antibodies specific for H-2L^d transformants[19,20]. Cell-surface antigen expression was measured quantitatively by radioimmunoassay. Two cloned lines transformed with the deleted *H-2L*^{d} gene, D3.4 and D3.8, were chosen for further analysis. Table 1 shows that clone D3.8 had as much H-2L^d on its surface as was found on the surface of clone T1.1.1 (an L-cell transformed with the complete *H-2L*^{d} gene, as described previously[3]). Clone D3.4, used in the biochemical studies described below, had slightly less H-2L^d molecules on its surface. Apparently, the deleted H-2L^d expressed after introduction into L-cells can be recognized by monoclonal antibodies.

To demonstrate that the deleted gene product was associated with β_2-microglobulin and shorter than the native protein, the deleted protein was isolated from the cell surface. Membrane

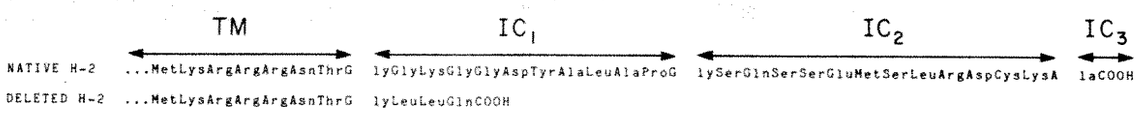

Fig. 2 Amino acid sequence of the transmembrane and cytoplasmic domains of the native and deleted H-2L^d molecules. The amino acid sequence of the transmembrane and cytoplasmic domains of the complete *H-2L^d* gene were predicted from DNA sequence analysis[4,5]. The four amino acids encoding the cytoplasmic domain in the truncated *H-2L^d* gene were derived from the second cytoplasmic domain of the murine *I-Aβ* gene[16].

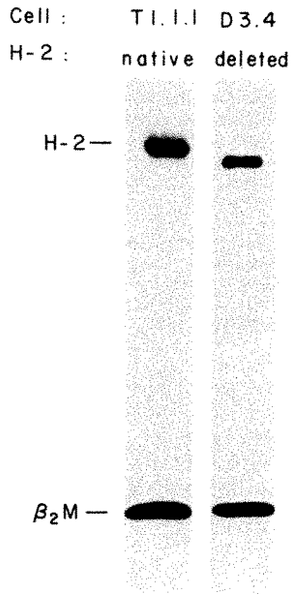

Fig. 3 SDS-polyacrylamide gel electrophoresis analysis of ^{125}I-labelled H-2L^d antigens immunoprecipitated from clone T1.1.1, expressing the complete *H-2L^d* gene, and clone D3.4 expressing the truncated *H-2L^d* gene. Cell-surface iodination with the ^{125}I was catalysed by lactoperoxidase[35]. The radiolabelled cells were lysed with 1% Nonidet P40 in 0.01 M Tris-HCl, *p*H 7.0, 0.15 M NaCl, 1 mM phenylmethylsulphonyl fluoride, 0.02 mg ml^{-1} ovomucoid trypsin inhibitor. Nuclear debris was removed from the lysates by centrifugation at 13,000*g* for 15 min at 4 °C. Further pretreatment of the lysates was done by centrifugation at 100,000*g* for 30 min and by pre-clearing with formalin-fixed *Staphylococcus aureus* bacteria (strain Cowan I) and with a preformed complex of mouse IgG and rabbit-anti-mouse IgG as described previously[36]. Precleared lysates were incubated for 3–4 h with a preformed complex with the monoclonal 30.5.7 and rabbit anti-mouse IgG at 4 °C and immunoprecipitates were removed from the lysates by centrifugation at 13,000*g*. Precipitates were resuspended in 0.2 ml Tris-HCl buffer with 0.5% deoxycholate sodium salt and spun through on a discontinuous gradient consisting of 0.4 ml of 10% sucrose, 0.5% Nonidet P-40 and 0.8 ml of 20% sucrose. SDS-polyacrylamide electrophoresis was carried out on discontinuous vertical slab gels according to a modification of the Laemmli procedure[37]. A gradient gel was made in 10–15% acrylamide. The gels were dried and exposed for 3 days. The figure shows H-2L^d antigens from clone T1.1.1 expressing the complete *H-2L^d* gene and clone D3.4 expressing the truncated *H-2L^d* gene.

BALB/c mice were immunized intraperitoneally with either wild-type VSV (10^7 plaque-forming units (PFU)) or influenza A/PR/8/34 virus (100 haemagglutinating units). One week later, the mice were killed and their spleens used as a source of virus-immune lymphocytes. Five-day secondary *in vitro* cultures were established with 5×10^6 primed lymphocytes and 1×10^6 irradiated BALB/c splenocytes which were infected with either 10 PFU tsG41 VSV or 10 EID_{50} (50% egg infectious dose) PR8 virus per cell in 17 mm Costar dishes with RPMI 1640 medium supplemented with 10% fetal bovine serum (FBS), penicillin, streptomycin, L-glutamine, and 5×10^{-5} M 2-mercaptoethanol. Primary allospecific CTLs were generated in 5-day cultures of 5×10^6 naive lymphocytes derived from either BALB/c or C-H-2^{dm2} mice cultured with 1×10^6 irradiated C3H or BALB/c stimulator cells using the same medium. Virus-specific or allo-specific effectors were collected and dispensed in duplicate at 1×10^6, 2×10^5 and 5×10^4 cells per V-bottom microtitre well (Linbro) in 0.1 ml minimum essential medium supplemented with 10% FBS, nonessential amino acids, penicillin, streptomycin, and L-glutamine. L-cell targets, detached by versene treatment, were divided into three aliquots and infected with either 10 PFU wild-type VSV or 10 EID_{50} PR8 virus, or not infected. Target cells were pulsed with 0.1 m Ci Na_2 $^{51}CrO_4$ for 1 h at 37 °C, incubated an additional 1 h, and then washed three times. L-cell targets were dispensed at 1×10^4 cells in 0.05-ml volumes into wells containing effectors, normal spleen cells to measure spontaneous release or 0.1 ml 5% Triton X-100 (to measure total releasable ^{51}Cr). Plates were centrifuged at 100*g* and then incubated at 37 °C for 5 h. Supernatants (0.1 ml per well) were collected and counted for ^{51}Cr release. Per cent specific release was calculated by the formula = 100 × (experimental c.p.m. − control c.p.m.)/(total c.p.m. − control c.p.m.)[15]. In order to present the results from multiple experiments, data were normalized such that lysis of T1.1.1 cells was 100%. Lysis of the T1.1.1 cells was equal to or greater than 70% in all experiments. Standard deviation and number of experiments (in parentheses) are indicated. Data are presented for lysis on appropriate targets (for example PR8 CTLs assayed on PR8 infected targets). Lysis on uninfected targets was always less than 10%.

proteins were labelled by lactoperoxidase-mediated iodination of the transformed cells. The proteins were immunoprecipitated by monoclonal antibody 30.5.7 which recognizes a determinant in the N/C_1 domain of the H-2L^d molecule[12]. The immunoprecipitates were analysed by SDS-polyacrylamide gel electrophoresis (Fig. 3). Both the deleted and wild-type proteins are associated with β_2-microglobulin. As expected, the molecular weight of the truncated H-2L^d antigen is significantly smaller than the complete *H-2L^d* gene product.

S_1 analysis of truncated H-2 transcripts

The fact that the protein is shorter does not guarantee that the mRNA has spliced correctly and that the protein has the expected sequence. To determine if the truncated gene product is the same as the predicted structure shown in Fig. 2, S_1 nuclease mapping was used to analyse total RNA obtained from transformants expressing the truncated gene product. This analysis was done using a single-stranded uniformly labelled DNA probe of high specific activity that was prepared by primer extension of a recombinant phage M13 DNA template. A *Bam*HI-RI fragment derived from the murine *I-Aβ* gene was cloned into the M13 phage (Fig. 4). After hybridizing mRNA with the labelled DNA probe, the reaction mixture was digested with S_1 nuclease and the products were analysed on denaturing polyacrylamide gels (Fig. 4). Only probes that had been hybridized to either mRNA from the transformed L-cells or from mRNA made from B cells expressing the *I-Aβ* gene were protected from S_1 nuclease digestion. An 89-nucleotide fragment was protected by mRNA isolated from clone D3.8 (Fig. 4, lane *D*). The protected fragment is identical to the fragment protected by mRNA (poly $(A)^+$) isolated from A20, a B-cell lymphoma expressing the *I-Aβ* gene (Fig. 4, lane *D*). Furthermore, the protected fragment is about the size (85 base pairs) predicted by comparison of the *I-Aβ* cDNA sequence[21] to the genomic *I-Aβ* sequence[16].

These results demonstrate that splicing of the cytoplasmic domain in the truncated *H-2L^d* mRNA occurs similarly to that of the *I-Aβ* mRNA normally expressed in a B-cell lymphoma, A20. Thus, the amino acid sequence of the COOH-terminus of the truncated *H-2L^d* product is predicted in Fig. 2. The deleted gene product has removed 25 amino acid residues from the native *H-2L^d* gene product and replaced these with three new residues.

Cytoplasmic part of H-2 in recognition

To determine the effects of deleting the cytoplasmic portion of the *H-2L^d* gene, L-cells expressing the native and truncated *H-2L^d* genes were used as targets for effector T cells in four systems. We and others have previously described the use of L-cells transformed with *H-2L^d* genes as targets for killer T cells[9–12]. Allospecific T cells recognize L-cells expressing the truncated gene product nearly as well as they recognize the

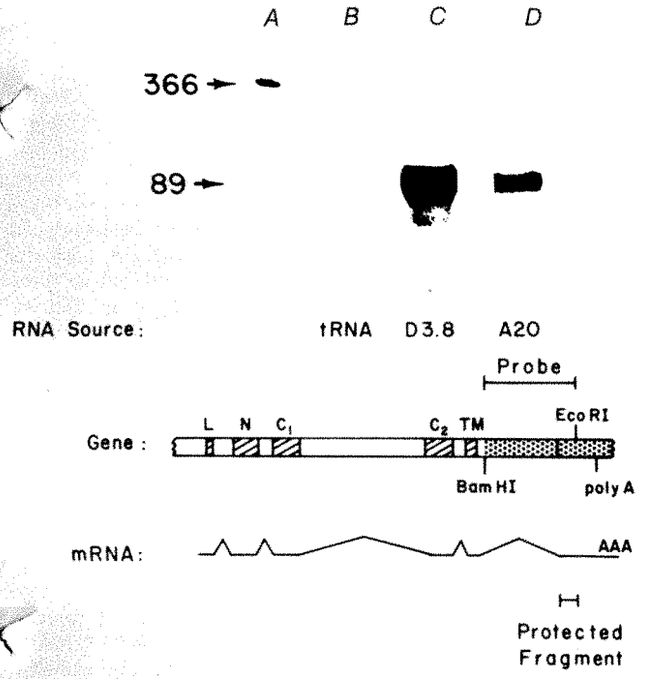

Fig. 4 Results of S_1 nuclease mapping analysis of mRNA isolated from clone D3.8 and B-cell lymphoma A20. A *Bam*HI–*Eco*RI fragment encoding the second cytoplasmic domain and 3′ untranslated region of the murine *I-Aβ* gene was cloned into M13mp9. After transfection of *E. coli* JM103 [38] appropriate recombinants, each containing the strand of the *I-Aβ* DNA that would serve as a template for the synthesis of a probe complementary to mRNA, were selected. Single-stranded DNA was recovered by using standard techniques after overnight incubation at 37 °C[38]. *A*, The probe fragment; *B*, tRNA hybridized with the probe and S_1 digested; *C*, mRNA from clone D3.8 hybridized and S_1 digested; *D*, mRNA from B-cell lymphoma A20 hybridized and S1 digested. **Methods:** A universal 24 base long primer was annealed with 0.3 μg of the single-stranded M13 recombinant; synthesis of the radiolabelled strand was then directed by the large fragment of DNA polymerase I using [α-^{32}P]dATP (400 Ci mmol^{-1}) and unlabelled dTTP, dCTP and dGTP. Synthesis of the second strand completed a unique *Hin*dIII site downstream from the insert. After synthesis of the second strand, digestion with *Hin*dIII released a ^{32}P-labelled single-stranded copy of the insert. This radiolabelled fragment was very different in size from the linear unlabelled template. The single-stranded radiolabelled probe was purified on a denaturing gel and recovered by electroelution[39]. mRNA was isolated from cells as described previously[40]. Samples containing 10 μg total mRNA from clone D3.8, 10 μg poly (A)$^+$ mRNA from A20 and 20 μg tRNA were hybridized overnight with 50,000 c.p.m. of single-stranded probe at 55 °C in 30 μl reaction mixture containing 75% (v/v) formamide[41]. Each reaction mixture was then digested with 700 U S_1 nuclease at 42 °C for 30 min[41,42] and the products were precipitated and analysed by electrophoresis on denaturing polyacrylamide sequence gels[43]. The size of the protected fragment was measured at 89 bases by co-migration with ^{32}P-labelled *Hin*f digested pBR322.

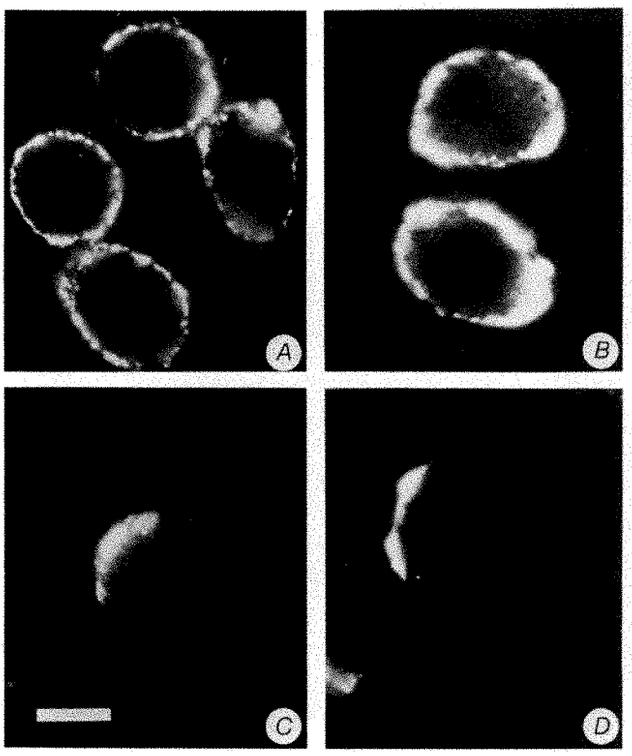

Fig. 5 T1.1.1 and D3.8 cells were detached from culture dishes with a rubber policeman and dissociated into individual cells with a Pasteur pipette in the cold room (4 °C). Cells were incubated with diluted mouse monoclonal antibodies (mixture of 30.5.7 and 28.14.8) in a sealed tube containing RPMI 1640 medium at 4 °C for 30 min. After washing in RPMI 1640 medium, cells were incubated with diluted fluorescein-conjugated goat anti-mouse immunoglobulin (Cappel) in RMPI 1640 medium at 4 °C for 30 min. After washing, an aliquot of cells was placed under a glass coverslip, sealed with nail polish and examined immediately by Zeiss Photomicroscopy III equipped with epiflorescent optics (Planapo, ×63). The rest of the cells were divided into two tubes, one kept at 4 °C, the other at 37 °C. At various times an aliquot of cells was removed and examined as above. For each time point, 300 cells were scored for redistribution of antigen. Photographs were made with Kodak Tri-X film (E1600) and developed in HC-110 dilution B for 12 min. Cells kept at 4 °C did not have a significant antigen redistribution at the end of the experiments. *A*, T1.1.1 and *B*, D3.8 immediately after staining at 4 °C. *C*, T1.1.1 and *D*, D3.8 after 2 h at 37 °C. Scale bar, 20 μm.

L-cells expressing the normal gene product (Table 2). Furthermore, influenza virus specific CTLs recognized virus-infected L-cells expressing the deleted *H-2L^d* gene product nearly as well as L-cells expressing the native *H-2L^d* gene product. By contrast, L-cells expressing the deleted *H-2L^d* product and infected with VSV were recognized less efficiently by the VSV specific killer T cells as the L-cells expressing the native H-2L^d molecule and infected by the virus (Table 2).

L-cells expressing the deleted *H-2L^d* gene product (clone D3.8, Table 1) appeared to bind the same amount of monoclonal H-2L^d antibody as the T1.1.1 cell (*H-2L^d*). Nevertheless, the possibility remained that small differences in the amount of H-2L^d on the cell surface had a significant effect on the recognition of these cells by VSV specific CTLs, even though these differences could not be measured by radioimmunoassay. To test this possibility we measured the ability of VSV specific CTLs to kill L-cells expressing significantly less native H-2L^d (Table 1, clone T123.8) than T1.1.1 cells (Table 1). These cells, expressing lower levels of H-2L^d, are killed just as effectively as cells expressing high levels of H-2L^d (Table 2). Thus, we conclude that the VSV specific CTLs are not able to recognize the truncated H-2 molecules as efficiently as they can recognize VSV associated with the normal *H-2L^d* gene product.

Cytoplasmic part of H-2L^d in capping

The H-2 molecule is normally uniformly distributed across the cell surface. Shortly after the addition of a monoclonal H-2 specific antibody and a fluorescent-labelled second cross-linking antibody, the H-2 molecules on the cell surface start to redistribute. Initially this redistribution involves the aggregation of the H-2 molecules into patches, presumably through the cross-linking of H-2 molecules by antibodies in the plane of the membrane. This event is followed by movement of these patches into a polar cap[22,23]. Other investigators have proposed that the latter is an energy-dependent process resulting from

association of transmembrane glycoproteins with cytoskeletal elements[24,25]. We investigated the nature of the interaction between the H-2 molecule and cytoplasmic proteins by studying the ability of the truncated H-2L^d molecule to make caps on the cell surface. Figure 5 shows the 'patching' and 'capping' of H-2L^d molecules expressed on the surface of T1.1.1 (complete *H-2L^d* genes) and D3.8 cells (truncated *H-2L^d* gene) after reaction with monoclonal antibody and fluorescent-labelled second antibody. Initially, the H-2L^d molecules are evenly distributed over the entire surface of the plasma membrane (Fig. 5*A, B*). After 2 h incubation the patches coalesce into a single cap on the surface of the T1.1.1 (Fig. 5*C*) and D3.8 (Fig. 5*D*) cells. To investigate if the rate of capping of the truncated H-2L^d antigen was different from the native molecule, a time course experiment was performed (see legend to Fig. 5). After 30 min incubation at 37 °C, 25% of T1.1.1 and 20% of D3.8 cells had capped. After 1 h at 37 °C, 50% of T1.1.1 and 46% of D3.8 cells had formed caps. After 1.5 h, 70% of T1.1.1 and 74% of D3.8 had capped. After 2 h at 37 °C, 80% of the T1.1.1 and 85% of the D3.8 cells had capped. Apparently the deleted *H-2L^d* gene product caps at precisely the same rate as the native H-2L^d molecule. Thus, we suggest that the interactions of the intracytoplasmic portion of the H-2 molecule with other proteins do not have a significant role in the movement of cell-surface antigens into caps.

Conclusions

We have constructed an *H-2L^d* gene whose product lacks the intracytoplasmic portion. The shortened protein is expressed on the cell surface. The product of this truncated *H-2* gene is efficiently recognized by allo- and influenza-specific cytotoxic T lymphocytes. Although VSV specific CTLs do not recognize this truncated H-2L^d molecule as efficiently as the complete *H-2L^d* product they are still able to recognize the truncated H-2 antigen. Thus, many of the cellular functions of the H-2 antigen can be performed by the truncated molecule. These findings suggest that interactions between the cytoplasmic proteins of the cell and the H-2 molecule do not have a critical role in the function of the H-2 molecule.

The nature of the interaction between viral antigens and H-2 antigens on the cell surface has puzzled immunologists for a long time. Several studies have indicated that some viral antigens and H-2 antigens are co-precipitated[26–28] or co-capped[29,30] by the appropriate antiserum. By contrast, no association has been identified between influenza virus antigens and H-2 antigens[31]. Presumably, these different results reflect differences in the interactions between particular viral antigens and the H-2 antigens. These differences might also account for the differences in the ability of the VSV specific CTLs and influenza specific CTLs to recognize cells expressing the truncated H-2 antigen. If interactions between viral and H-2 antigens do occur, these interactions must be quite subtle. Thus, small differences in experimental conditions may have a significant effect on the apparent function of an H-2 molecule. The weakness of these interactions also raises the question of which of these interactions are important to the animal rather than those detected in tissue-culture conditions. The introduction of the truncated *H-2* gene described here directly into the mouse genome may allow a direct test of this question.

The truncated *H-2L^d* gene product and the wild-type H-2L^d molecule function identically in most of the cellular assays, suggesting that the structure of the protein is not grossly altered by the deletion of the cytoplasmic portion. To test whether a physical parameter, the ability of these molecules to form caps, is affected by changes in the cytoplasmic portion we compared the rates of the cap formation on cells expressing the two proteins. We observed no differences in the rate of capping between the truncated and complete H-2L^d antigen. We conclude that if interactions between other cellular proteins and the intracytoplasmic portion of the H-2 molecule have an important role in cap formation, then these interactions are non-specific. Co-capping experiments of viral antigens and truncated H-2L^d molecules will be examined to determine if the truncated H-2L^d is able to co-cap viral antigens as well as the wild-type antigen co-caps viral antigens.

We thank Ms J. Borst for help with the immunoprecipitation, Ms Lisa Liu for technical assistance and Ms T. Broderick for preparation of the manuscript. Tripartite structure of the *Brassica campestris* mitochondrial genome

Jeffrey D. Palmer*‡ & Clark R. Shields†

Physical mapping studies indicate a novel sequence arrangement, consisting of three circular chromosomes, for the mitochondrial genome of Brassica campestris *(Chinese cabbage, turnip). A master chromosome, 218 kilobases (kb) long, contains the entire sequence complexity of the mitochondrial genome, including two copies of an ~2-kb element present as direct repeats separated by 135 and 83 kb. The two smaller circles are 135 and 83 kb in size, contain one copy each of the 2-kb repeat element, and are postulated to interconvert with the master chromosome via a co-integration–resolution pathway mediated by reciprocal recombination within the 2-kb repeat.*

HIGHER plant mitochondrial genomes are unusually large and variable in size, ranging from ~200 kilobases (kb) in *Oenothera*[1] and *Brassica*[2,3] to almost 2,500 kb in muskmelon[4]. The way in which this DNA is organized into discrete molecules is unclear[5–7]. Electron microscopic analysis of mitochondrial DNA isolated from native plant tissue reveals a broad size range of molecules, primarily linear with a low percentage of circles[8–10]. A much larger percentage of the mitochondrial DNA from cultured cells can be isolated as intact circles, with predominant size classes in the range 2–30 kb[11–13]. Several models have been proposed which attempt to reconcile the large kinetic and restriction complexities of plant mitochondrial DNA with the failure to find a discrete size class of molecules large enough to accommodate this information (see refs 5 and 6 for a review). At one extreme, it has been proposed that the plant mitochondrial genome may exist as a collection of different size classes of circular molecules, with each size class containing a distinct, non-overlapping subset of the total sequence complexity of the genome[14]. Alternatively, it has been suggested that the genome is organized primarily as a single large linkage group, with frequent recombination and rearrangement leading to the array of smaller molecules more easily isolated and observed via electron microscopy[15]. Data in support of these and other models are hardly overwhelming, although the last model is consistent with restriction mapping of corn mitochondrial DNA[16–18], where several linear linkage groups have been determined that are larger than any of the observed circular molecules[9].

We now report the first complete restriction map for a higher plant mitochondrial genome, that of *Brassica campestris* (Chinese cabbage, turnip). The model most consistent with our mapping data is that this genome is organized into three physically distinct circular molecules. The largest circle of 218 kb bears the entire sequence complexity of the genome and thus constitutes a 'master' chromosome, and the two smaller circles contain distinct, 135-kb and 83-kb subsets of the master molecule. These three chromosomes seem to interconvert via reciprocal recombination across the major repeat element present on all three molecules.

Physical mapping studies

A clone bank containing 96% of the *B. campestris* mitochondrial genome was constructed by inserting *Pst*I and *Sal*I fragments into the plasmid vector pUC8 (ref. 19). Each of these cloned fragments was labelled with ^{32}P and hybridized to nitrocellulose filters containing single digests of total mitochondrial DNA with each of five enzymes (*Pst*I, *Sal*I, *Bgl*I, *Kpn*I, *Nru*I) and also selected double digests with various combinations of these enzymes. The mapping strategy is illustrated in Fig. 1. A cloned *Sal*I fragment of 28 kb (S28) hybridized to eight *Pst*I fragments, ranging in size from 10.2 to 0.9 kb (Fig. 1). Hybridization to a *Sal*I–*Pst*I double-digest lane indicated that six of these fragments (9.7, 7.5, 2.9, 2.0, 1.3 and 0.9 kb in size) are uncut by *Sal*I, and thus lie completely internal to S28, while P10.2 and P5.7 are cut by *Sal*I and thus overlap the junctions between S28 and two flanking *Sal*I fragments (Fig. 1). P10.2 hybridized to a double-digest fragment of the same size (2.4 kb) as one of the two terminal S28 double-digest fragments. We conclude, therefore, that this fragment represents the overlap between S28 and P10.2, and that the other terminal S28 double-digest fragment, of 2.2 kb, must represent its overlap with P5.7. P10.2 also hybridized to internal *Sal*I fragments of 4.4 and 2.8 kb and to a second *Sal*I fragment, S10.1, cut by *Pst*I (Fig. 1). The length of the overlap between P10.2 and S10.1 is given by the 0.6-kb double-digest fragment to which they both hybridize (Fig. 1). Thus, using only three hybridizations, a region of 60 kb of DNA, from P19.4 to P5.7, was mapped for these two enzymes (Fig. 2).

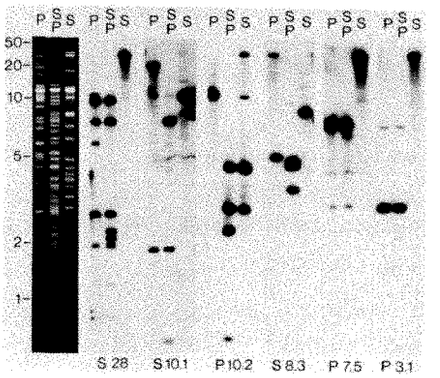

Fig. 1 Representative mitochondrial DNA mapping hybridizations. Left-hand panel: DNase I-purified[25] mitochondrial DNA from *B. campestris* was digested with *Pst*I (P), *Sal*I–*Pst*I (SP) and *Sal*I (S), and fragments were separated by electrophoresis in a 0.7% agarose gel[38]. The size scale on the left is in kb and was determined using λ phage DNA restriction fragment markers generated with *Sal*I, *Hin*dIII and *Eco*RI. Right-hand panels: six cloned mitochondrial DNA restriction fragments were each labelled with ^{32}P by nick-translation[39] and hybridized[38] to a replica nitrocellulose filter imprint[38] of the gel shown in the left panel. In this and the other figures, and also in the text, a given mitochondrial DNA restriction fragment, or a plasmid containing the fragment, is designated both by a letter, indicating the enzyme used to generate the fragment (P = *Pst*I, S = *Sal*I, B = *Bgl*I, K = *Kpn*I, N = *Nru*I) and a number, indicating the size of the fragment in kb.

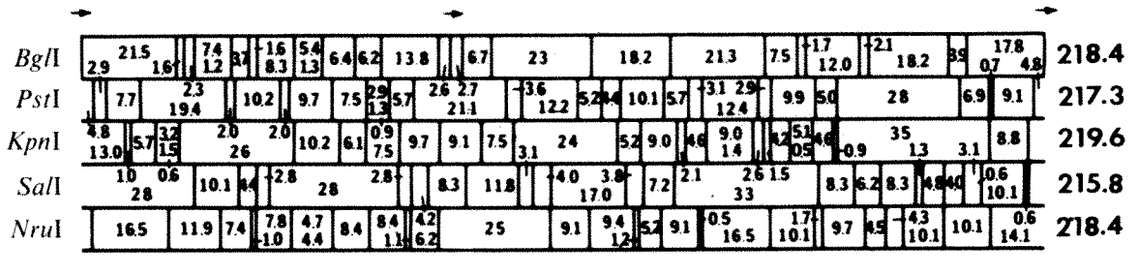

Fig. 2 Restriction map of the master chromosome of *B. campestris* mitochondrial DNA. The circular map for the largest mitochondrial linkage group, containing the entire sequence complexity of the genome, is shown linearized at the *Bgl*I site internal to the 2-kb repeat sequence. Arrows indicate the position and relative orientation of the two copies of the 2-kb repeat present on this linkage group. The numbers at the right-hand end of the map indicate the summation of the restriction fragments for each of the enzymes marked at the left-hand end.

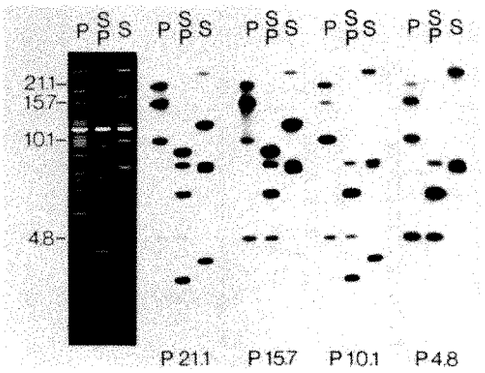

Fig. 3 Hybridization analysis of the major repeat sequence of *B. campestris* mitochondrial DNA. The four *Pst*I clones indicated were each hybridized to replica nitrocellulose blots of mitochondrial DNA digested with *Pst*I (P), *Sal*I–*Pst*I (SP) and *Sal*I (S).

In control *Pst*I–*Pst*I or *Sal*I–*Sal*I hybridizations, several cloned fragments hybridized to one or more fragments in addition to the expected fragment of the same size of the cloned insert. Except for one special case, described in detail below, these extra hybridizations were all very weak and did not confuse interpretation of the hybridization results in terms of constructing a map. In several cases, reciprocal cross-hybridizations clearly indicated that these weak hybridization signals result from small repeated sequences present in two or more copies in the mitochondrial genome (compare P7.5 and P3.1 hybridizations in Fig. 1). In other cases, the weak, additional hybridizations were to fragments larger than the probe fragment and sometimes could not easily be assigned to major fragments visible in the stained gel (see S10.1 and S8.3 hybridizations in Fig. 1). These hybridization signals could result either from slight partial digestion products, from the presence of minor repeat elements within the major bands, or from microheterogeneity in the DNA, resulting in very faint bands not clearly visible in the stained gel.

2-kb Repeat element

The major cross-hybridization between cloned fragments was observed with four *Pst*I fragments, each of which hybridized to itself and to the other three *Pst*I fragments (Fig. 3). The sequence common to these four fragments has a minimum size of 0.6 kb, as defined by common *Bam*HI and *Bgl*I sites, and a maximum possible size of 3.2 kb, as defined by *Eco*RI digestion (Fig. 4). Hybridization of each of the four *Pst*I fragments to *Bam*HI and *Bgl*I digests of all four clones (normalizing insert cross-reactions to vector hybridizations) allows a very rough quantitative estimate of the size of this repeat as 2 ± 1 kb. For convenience, this element will henceforth be referred to as the '2-kb repeat'.

Three of the 2-kb repeat-containing *Pst*I fragments, P21.1, P15.7 and P4.8, are clearly substoichiometric relative to the rest of the *Pst*I fragments as judged both by direct visualization of stained gels (Figs 1, 3) and densitometric scanning of a *Pst*I digest (Fig. 5). The fourth 2-kb repeat-containing fragment, P10.1, co-migrates with a second, non-identical fragment and its stoichiometry could not be evaluated directly. It should be emphasized that, taking into account degradation effects on the larger fragments, all the remaining *Pst*I fragments fall into a unimolar stoichiometric series except for one doublet (P5.7), one triplet (P2.9), and a bright band at 11.3 kb which corresponds to an extrachromosomal, linear mitochondrial DNA plasmid described previously[3].

The gels and gel scan suggest that P21.1 and P4.8 are present in submolar amounts relative to P15.7 (Figs 1, 3, 5). Direct support for this conclusion can also be gained from quantitative consideration of the hybridizations shown in Fig. 3. If P21.1 and P15.7 were present in equal molarity within the mitochondrial genome, then, assuming that single-stranded probe lengths are short relative to insert sizes, a P21.1 probe should hybridize to itself approximately 1.5 times (21.1 divided by 14—the approximate size of the region of homology between P21.1 and P15.7; see Fig. 4) more intensely than to P15.7, while a P15.7 probe should hybridize to itself only 1.1 times (15.7/14) more intensely than to P21.1. In fact, visual inspection reveals that P21.1 hybridizes to itself somewhat less intensely than to P15.7, while P15.7 hybridizes to itself significantly more intensely than to P21.1 (Fig. 3). Quantitation of these hybridization signals by densitometry and measurement of the area under each curve indicates that P15.7 is actually present in about twice the molarity of P21.1. These calculations can only be approximate for two reasons. First, the size of the repeat is not accurately known, and second, significant degradation of the DNA on the filter results in diminished hybridization signals for the large fragments relative to small ones. Similar pairwise comparisons of the hybridizations in Fig. 3 lead us to conclude that P10.1 is also present in approximately twice the concentration of P21.1, and that P15.7 and P10.1 are approximately equimolar and are approximately twice as abundant as P4.8. Thus, we conclude that the four *Pst*I fragments which contain the 2-kb repeat are all submolar and that they can be further subdivided into two groups, with P15.7 and P10.1 being present in approximately equal molarity and at roughly twice the concentrations of P21.1 and P4.8.

Multicircular mitochondrial DNA

The 2-kb repeat is present on all four substoichiometric *Pst*I fragments. In addition, each *Pst*I fragment is identical, on one side of the repeat, to one of the other three fragments and on the other side of the repeat to a second one of the other three (Fig. 4). In other words, the 2-kb repeat is flanked by four paired combinations of four unique sequences. The two lower molarity substoichiometric fragments, P4.8 and P21.1, are equivalent in sequence complexity to the higher molarity pair, P15.7 and P10.1, and the two pairs are interconvertible by a single reciprocal cross-over within the 2-kb repeat.

The overall arrangement in the genome of these four substoichiometric, repeat-containing *Pst*I fragments was determined by completing the chromosomal 'walk' described above. These hybridizations generate a single, circular linkage group

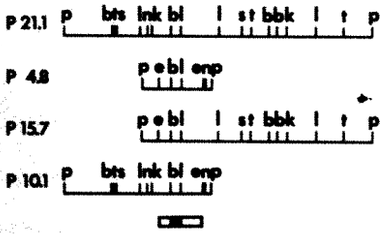

Fig. 4 Restriction maps of the four, 2-kb repeat-containing, substoichiometric *Pst*I fragments of *B. campestris* mitochondrial DNA. Cleavage sites for *Bam*HI (b), *Bgl*I (l) *Bst*EII (t), *Eco*RI (e), *Kpn*I (k), *Nru*I (n), *Pst*I (p) and *Sal*I (s) were mapped by appropriate double and triple digestions of plasmids containing each of the four *Pst*I fragments indicated. All cleavage sites are shown for all enzymes except for *Eco*RI, which produced many small fragments with the three largest clones. However, as *Eco*RI cleaves P4.8 only twice, defining the maximum boundaries of the repeat sequence as presently mapped, we show these two sites as they occur on P4.8, P10.1 and P15.7. The repeat sequence (bl) is flanked by four paired combinations of four unique sequences (pbtslnk, lstbbkltp, pe, enp). The solid bar indicates the minimum extent of the repeat sequence and open extensions of the bar its maximum extent.

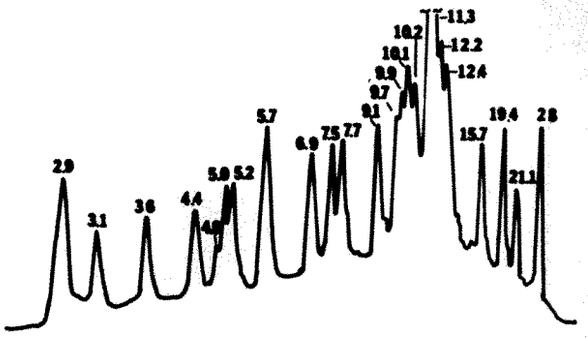

Fig. 5 Stoichiometry of *Pst*I fragments of *B. campestris* mitochondrial DNA. A negative of a gel similar to those shown in Figs 1 and 3 was densitometrically scanned in a Beckman DU spectrophotometer at an absorbance wavelength of 600 nm.

(Fig. 2) that accounts for every fragment for all five enzymes except for two fragments with each of *Pst*I (P15.7 and P10.1), *Kpn*I (K11.0, a doublet), *Nru*I (N35 and N3.9) and *Sal*I (S28 and S8.1). This circle contains the entire 218-kb sequence complexity of the *B. campestris* mitochondrial genome, including two copies of the 2-kb repeat present in direct orientation within P21.1 and P4.8 (Fig. 2). When the chromosomal walk is started at P15.7 or P10.1 and continued outwards in both directions, smaller circular linkage groups are generated, of 135 and 83 kb, respectively, each containing just one copy of the 2-kb repeat (Fig. 6).

The *Kpn*I, *Nru*I and *Sal*I fragments not accounted for by the large circle (Fig. 2) are those that span the 2-kb repeat on the two small circles (Fig. 6). It was not possible to evaluate the stoichiometry of the repeat-containing *Sal*I fragments (Figs 1 and 3) and *Kpn*I fragments due to their co-migration with other fragments. However, all four of the repeat-containing *Nru*I fragments are well separated and appear substoichiometric with approximately the same molarity relationships as described for the corresponding *Pst*I fragments (data not shown). *Bgl*I cuts within the repeat (Figs 2, 4, 6), thus no substoichiometric *Bgl*I fragments were observed.

Together, the two small circles contain the entire sequence complexity of the master chromosome. Figure 6 presents a simple model for the interconversion of these three circles via reciprocal recombination between directly oriented 2-kb repeat elements. Two recombination reactions are shown: intramolecular recombination between repeat elements present on the master chromosome will lead to its resolution into the two small circles, and the converse, intermolecular recombination between 2-kb repeats on the small circles will lead to their cointegration to form the master circle. This model portrays only two of essentially an infinite number of possible recombination reactions. Each of the two small circles could recombine with either repeat element on the large circle, generating circles of 353 or 301 kb. Recombination could occur between identical circles, leading to circular dimers. Higher order reactions could involve any of these multimeric molecules and also the simpler molecules shown in Fig. 6, leading to larger and larger circles, *ad infinitum*.

The simplest alternative to the three-circle model shown in Fig. 6 is a circular dimer model[20,21]. Head-to-head 436-kb circular dimers formed by intermolecular recombination between the P4.8 repeat present on one 218-kb circle and the 21.1-kb repeat present on a second circle would contain all four of the repeat orientations shown in Fig. 6. However, a collection of 218-kb monomers and head-to-head dimers would have higher levels of the P4.8 and P21.1 repeats (present on both monomers and dimers) than of the P15.7 and P10.1 repeats (present on dimers only). Even in the limit case, where all of the mitochondrial DNA existed as head-to-head 436-kb dimers, the four repeats would be equimolar. As P15.7 and P10.1 are approximately twice as abundant as P4.8 and P21.1, we conclude that the simplest model consistent with both mapping and stoichiometry relationships is the three-circle model (Fig. 6). While we believe it likely that most of the mitochondrial DNA exists in one of these three circular forms, this does not preclude a small percentage of the DNA existing as circular dimers or

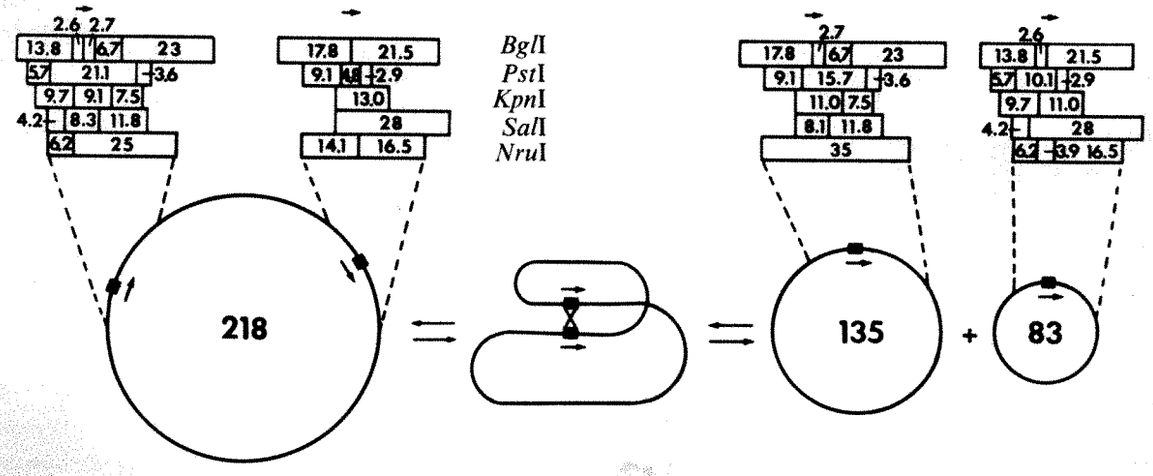

Fig. 6 Top, restriction maps of the four regions of the mitochondrial genome which contain the 2-kb repeat sequence. Bottom, predicted organization of the *B. campestris* mitochondrial genome into three circular molecules and their interconversion via recombination within the 2-kb repeat. Solid boxes indicate the position of the repeat and arrows its orientation.

any of the other multimers described in the preceding paragraph.

Regardless of the ultimate size of the molecules on which they are present, P4.8 and P21.1 seem to be inextricably physically linked and thus must be present in equal molarity. As P15.7 and P10.1 are present at roughly twice the concentration of P21.1 and P4.8, it can be concluded that there are approximately two molecules of the two small circles for each molecule of the master chromosome. That P15.7 and P10.1, and thus the circles they represent, are approximately equimolar suggests that the master chromosome may be the replicating molecule within the mitochondrion. According to this hypothesis, most recombination events would occur intramolecularly, generating the two small circles from the master chromosome, and thereby maintaining equal levels of these two circles. Clearly, however, fragment stoichiometries, approximate as they are, can provide only suggestive evidence concerning the direction of recombination and replication, and more direct experimental tests are necessary to provide conclusive answers.

Discussion

The organization of the *B. campestris* mitochondrial genome into three physically distinct circular chromosomes maintained via recombination across a common repeat element is a novel pattern of mitochondrial DNA sequence organization. While a great diversity of small extrachromosomal molecules have been found in the mitochondria of plants and fungi, the main mitochondrial genome in all eukaryotic organisms characterized to date consists of a single molecular species, usually circular, although occasionally linear[6,7,22].

Is the tripartite structure of mitochondrial DNA from *B. campestris* typical of other plant mitochondrial genomes, most of which are considerably larger? Sets of four repeat-containing restriction fragments having paired combinations of unique flanking sequences, completely analogous to those characterized here, have been found in corn[21], wheat[23] and spinach (D. B. Stern and J.D.P., unpublished data). In corn, extensive restriction mapping of the 569-kb mitochondrial genome indicates that the bulk of the genome may be organized in a tripartite fashion similar to that of *Brassica*, although secondary recombination events outside the major repeat sequence appear to generate an extra diversity of circular size forms not seen in *Brassica* (ref. 21 and D. M. Lonsdale, personal communication). Recent work also indicates that similar processes of intramolecular recombination and excision may lead to the dissolution of the 65-kb *Neurospora* mitochondrial genome into 22- and 43-kb circles in certain *stopper* mutants[24].

The process of recombination between repeated sequences to give alternate states of *Brassica* mitochondrial genome organization—either two small circles or one large co-integrate circle—is analogous to the process of λ phage integration–excision into the *Escherichia coli* chromosome[26] and that of bacterial transposable element cointegrate formation–resolution[27]. By analogy to these and mechanistically related specialized site-specific recombination systems[28–31], we speculate that there may be a specialized recombination system, possibly encoded within the *Brassica* mitochondrial genome and perhaps even physically linked to the 2-kb repeat sequence, which mediates recombination between specific recombination sites embedded within the 2-kb repeat. We are now examining these hypotheses through sequence studies of the 2-kb repeat and by testing its ability to act as a substrate in a heterologous site-specific recombination system[32].

Further analogy, to processes of low-frequency, secondary site recombination between λ DNA and the *E. coli* chromosome[26], leads to the prediction that recombination may also occur between the putative strong recombination site located in the 2-kb *Brassica* repeat and weaker recombination sites located elsewhere in the genome. This possibility will be studied in *Brassica*, and may be related to the high levels of small circular mitochondrial DNA molecules observed in suspension cell cultures of other plant species[11–13]. We hypothesize that these abundant small circles may result from secondary recombination processes which normally occur at very low frequency in native plant tissues but which are intensified when plant cells are cultured *in vitro*.

The *B. campestris* mitochondrial genome is relatively small compared with the mitochondrial genomes of most other higher plants. Therefore, we expect that it will serve as an excellent model system in which to examine many fundamental questions concerning the structure, expression and function of plant mitochondrial genes and also the precise involvement of the mitochondrial genome in cytoplasmic male sterility[3,5,6]. In addition, important evolutionary questions relating to the mode and tempo of plant mitochondrial DNA divergence can now be directly addressed. It is well known, for example, that animal mitochondrial DNA evolves extremely rapidly at the primary sequence level but is highly conserved in gene arrangement, whereas fungal mitochondrial DNA is characterized by a high degree of genomic rearrangement[7,33]. In contrast, little is known about how plant mitochondrial DNA evolves, although limited observations suggest that it may be relatively conserved among mitochondrial DNAs at the sequence level, with a moderate tendency to rearrange[7,34]. We are now addressing these questions by comparing restriction maps of mitochondrial DNA from *B. campestris* and from five other species in the genus *Brassica*. Evolutionary divergence values are well established for the chloroplast DNAs of these species[35], thus these experiments should also give valuable information on relative rates of sequence change in the two cytoplasmic organelles. Finally, we point out the utility of a complete physical map for furthering our understanding of the nature and pattern of integration of chloroplast DNA sequences within plant mitochondrial DNAs[17,36,37].

We thank W. F. Thompson for providing laboratory facilities for this research, the Department of Vegetable Crops at the University of California at Davis for financial assistance, D. M. Lonsdale and M. W. Gray for communication of results before publication, and R. B. Flavell and M. E. Zolan for helpful discussion. This is CIW-DPB publication 838.

On the far-infrared excess of Vega

Paul M. Harvey, Bruce A. Wilking & Marshall Joy

Astronomy Department, University of Texas at Austin, College of Natural Sciences, 15.308 R. L. Moore Hall, Austin, Texas 78712, USA

The Infrared Astronomy Satellite (IRAS) has recently detected a compact far-infrared emission source associated with Vega (α Lyrae)[1]. This flux appears to be thermal emission from dust heated by the visual/UV luminosity of Vega. Although circumstellar dust is commonly associated with young, early-type stars[2], the characteristics of the emission from Vega are quite atypical. The essential difference is the relatively low temperature of the dust for the observed source size. This low temperature implies that the dust grains producing the far-infrared emission must be very efficient 60/100-μm emitters and must, therefore, be much larger than typical interstellar and circumstellar dust grains. To place more limits on the properties of this far-infrared emission region, we observed Vega at 47 and 95 μm with the Kuiper Airborne Observatory (KAO) on the night of 12–13 August 1983. We report here confirmation of the IRAS results and that the source size may be as large as 46 arc s along some axis.

We used a 3 spatial × 2 spectral element array radiometer described in detail by Wilking *et al.*[3]. Briefly, this system measures simultaneously the flux at two wavelengths from three circular regions of sky which lie along a line in cross-elevation. The centre-to-centre separation between the beams is 1 arc min. The cross-elevation direction was rotated 15° to the north-west and south-east from a line parallel to declination. We observed at 47 μm ($\Delta\lambda = 20$ μm) and at 95 μm ($\Delta\lambda = 80$ μm). In addition to the normal short-wavelength blocking provided by a diamond scatter filter and various crystalline materials[4,5], we added a layer of 0.003-inch black polyethylene on the outside of the radiometer to eliminate any possible short-wavelength leaks in the standard filtering. The beams are roughly gaussian in shape with half-power widths of 30 and 43 arc s respectively at 47 and 95 μm. The oscillating secondary chopper of the KAO was operated with a throw of 3 arc min in cross-elevation.

The central of the three beams was placed on the visible image of Vega so that the outer beams observed points roughly 1 arc min to the north and south. The measured flux densities in all six channels after about 4,000 s integration time are listed in Table 1. The observations were calibrated relative to IRC+10420. We have measured the flux density of IRC+10420 relative to Mars, S140 (ref. 6), and NGC7027 (ref. 7), on several flights and find values of 1,270 ± 135 and 360 ± 70 Jy, respectively at 47 and 95 μm. (These measurements have also refined our estimates for the flux density of S140 to 6,600 and 6,900 Jy respectively.)

It is clear from Table 1 that far-infrared flux is definitely seen from Vega at a level similar to that reported by Aumann[1]. It is also apparent that no flux was seen in the detectors which viewed positions 1 arc min away from the star to a 2σ limit of roughly one-third that seen on Vega itself. A more stringent limit on the far-infrared surface brightness at a radius of 1 arc min from Vega may be obtained by averaging the four measurements taken off the peak. This leads to an average 50–100 μm flux density of 0.45 ± 0.35 Jy, a factor of 10 or more fainter than the central value. Therefore, the source radius is certainly less than 1 arc min, consistent with the results of Aumann *et al.*[1].

Table 1 Observed flux densities (Jy)

	1 min South	Central	1 min North
47 μm	0.55 ± 0.6	4.6 ± 0.85 (±1.25)	0.45 ± 0.65
95 μm	0.9 ± 0.65	4.5 ± 0.8 (±1.40)	−1.1 ± 1.45

Absolute calibration uncertainty ±20% at 50 μm; ±25% at 100 μm. The total uncertainty, absolute plus statistical, is shown in parentheses.

If we combine our subarc min resolution data with those of Aumann *et al.*[1], we can place better limits on the source size. For comparison, we have calculated the flux densities at our effective wavelengths of 47 and 95 μm using the IRAS flux densities and assuming a black-body spectral shape. These are then 8.2 Jy at 47 μm and 7.3 Jy at 95 μm. Our observed flux densities (Table 1) are 0.56 ± 0.15 and 0.62 ± 0.21 of the IRAS values at 47 and 95 μm, where the errors include all our uncertainties and a nominal 10% error for the IRAS data. Within 3σ error limits these are consistent with unity. But we may derive a rough estimate of source size by assuming that the lower flux densities seen by our smaller beams result because the source size is comparable to our beam size. In this case, the diameter of a uniform disk large enough to produce the above flux ratios is 42^{+10}_{-7} arc s and 53^{+18}_{-10} arc s, respectively, at 47 and 95 μm. Although the formal error limits on the source size are quite large, the fact that our observed colour temperature of 79 K is less than the IRAS value of 85 K, is also consistent with the idea that the source size is comparable to our beam size. In such a case, the larger 95 μm beam would be expected to measure a greater fraction of the total flux than the 47 μm beam, leading to a lower colour temperature than found by IRAS. In the following discussion we will assume a source diameter of 46 ± 10 arc s based on our flux measurements.

This small source size implies dust grains which have an absorption efficiency at visual–UV wavelengths nearly equal to their emission efficiency in the far-infrared as noted already by Aumann *et al.*[1]. If we equate the energy absorbed by grains at a radius of 23 ± 5 arc s with the energy re-emitted, we find that the ratio of Planck-averaged absorption efficiency to emission efficiency is 2.8 ± 1.3. This is in extreme contrast to typical values for interstellar dust of 100–1,000 (refs 8, 9 and P. Makinen, N. J. Evans, P. M. H. and M. A. Kutner, in preparation). This near equality of visible and far-infrared efficiencies implies that the 47 μm and 95 μm emission efficiencies are almost certainly equal except for any small effects dependent on dust composition. Therefore, the IRAS colour temperature of 85 K is probably quite close to the physical dust temperature.

This high emission efficiency places strong lower limits on the size of the grains seen in emission. No calculations of $\lambda \sim 100$ μm emission efficiency for 'large' grains have been found in the literature, but a rough estimate may be obtained from calculations of small grain properties at shorter wavelengths. For instance, the data of Aannestad[10] show for typical interstellar grains that as soon as the wavelength becomes larger than 1–1.5 times the grain diameter, the emission efficiency drops rapidly from unity. Scaling to $\lambda \sim 100$ μm, we expect the grains around Vega to have a diameter $d \geq 20$ μm in order to have a far-infrared emission efficiency as large as one-third the short-wavelength absorption efficiency.

We may estimate the minimum mass necessary to produce the observed emission assuming the particles have unit emissivity, a radius $r \geq 10$ μm, and density of 2 g cm^{-3}. This mass is $M = 10^{24}$ g, comparable to the mass of a small satellite in the solar system. The mass required to produce the observed level of emission scales linearly with assumed particle size. Therefore, although it is possible to produce the observed flux density with a single large 'particle', the required mass is of the order of $10^6\ M_\odot$.

The above limit on grain size, $d \geq 20$ μm, is a very strong limit based only on the assumption that the emission is thermal and that the grain emissivity is a reasonable function of wavelength. An additional size limitation is imposed by the Poynting–Robertson effect[11] which will cause grains of diameter 20 μm and density 2 g cm^{-3} to spiral in to the central star in a time of 8×10^6 yr, assuming $L_* = 58\ L_\odot$ (ref. 12), a source radius

© 1984 Macmillan Journals Ltd

$r \sim 180$ AU and a distance for Vega of 8 pc (ref. 13). Aumann *et al.*[1] have summarized a number of arguments which imply that the grains must have been produced at the time of formation of Vega. Therefore, the grains must be even larger than $d = 20$ μm if the age of Vega is $>10^7$ yr.

We have confirmed the far-infrared excess of Vega found by the IRAS survey. From a comparison of flux densities in our beam relative to the IRAS data we find evidence that the source has a diameter of the order of 46 arc s. This is roughly twice that found by IRAS using deconvolution of larger beam data. Resolution of this disagreement must await further observations: it may result either from observational errors or from a source brightness distribution which is more complicated than the assumed uniform, spherical geometry.

These data also confirm the fact that the grains around Vega must be much larger than typical interstellar grains ($a \sim 0.1$ μm). Therefore, some form of grain growth must have occurred. The Poynting–Robertson effect places a limit on the grain radius a (μm) and the time since grain formation in units of 10^6 yr, t_6, such that $a \sim t_6$ for a cloud diameter of 46 arc s. Further observations of the Vega dust cloud and theoretical modelling of grain growth should provide important insight into the kind of processes which may have led to the even greater 'grain' growth in the Solar System.

We thank the entire KAO staff for their help in obtaining the observations presented here. We also thank C. Beichman and the IRAS science team for several useful discussions.

Nitrous oxide (N_2O) is of prime interest for understanding stratospheric chemistry[1] and the energy budget of the troposphere[2]. Atmospheric N_2O has been considered to be mainly regulated by biological processes in soils[3–6]. However, the oceans have an important role in the geochemical cycle of N_2O both as a reservoir and a reaction site[7–12]. We report here the first ^{15}N abundance data on dissolved N_2O collected from the eastern tropical Pacific Ocean where active nitrogen transformation has been proposed to occur[12–16]. Our ^{15}N data provide additional evidence for the hypothesis that the subsurface waters act as a source of N_2O and that the extremely oxygen-depleted waters act as a sink.

§ Present address: Laboratory of Biogeochemistry and Sociogeochemistry, Mitsubishi-Kasei Institute of Life Sciences, 11 Minamiooya, Machida-shi, Tokyo 194, Japan.

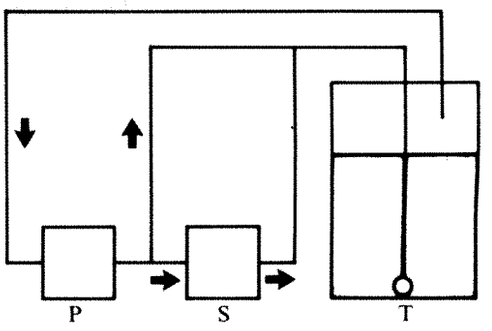

Fig. 1 The device used for extraction and collection of dissolved N_2O from seawater samples. Approximately 100 l of seawater was introduced into a stainless steel tank (T, ~150 l in volume), which had been filled with Ar. The gas above the sample water was circulated by the aid of a pump (P) through a sintered glass ball to facilitate emission of N_2O into the gas phase. A portion of the circulation gas goes through a bypass where N_2O is adsorbed on a molecular sieve 5A column in a sampling device (S) whose detail was described in ref. 17. Complete collection of N_2O was achieved within 12 h. For safety, the circulation was continued for 15 h.

Yoshida and Matsuo[17] first introduced the nitrogen isotope ratio to assess the geochemical cycle of N_2O. In their study, they maintained that basic knowledge of the nitrogen isotope ratio of dissolved N_2O in the oceans would improve our understanding of the global budget of N_2O. The existing data on dissolved N_2O concentration in oceanic waters suggest that N_2O is produced in association with bacterial nitrification in subsurface waters and consumed by denitrification occurring in extremely oxygen-depleted waters[8,9,11–13]. Low oxygen tension favours the production of N_2O associated with nitrification[18–20]. We therefore focused on the nitrogen isotope ratio of N_2O dissolved in water masses within and at the boundaries of the oxygen minimum zone.

Seawater samples were collected with 23-l Niskin bottles from various depths at six stations of the eastern tropical Pacific Ocean on legs 2 and 3 of KH-82-5 Cruise of RV *Hakuho Maru*, University of Tokyo[21]. Five seawater samples collected at 2-m depth intervals were successively and carefully introduced, without exposure to air, to a stainless steel tank which had been flushed and filled with argon. Dissolved N_2O was then extracted and collected on a molecular sieve 5A column using a device illustrated in Fig. 1. The nitrogen isotope ratio of the N_2O was determined later in the laboratory by a method described elsewhere[17]. The accuracy of the data presented here is estimated to be within ±3% for concentration and ±0.2‰ for $\delta^{15}N$ of N_2O both in the atmosphere and in the ocean.

The vertical profiles of N_2O were similar to those reported by other workers[9,11–13,16]; N_2O increased with depth, attained a maximum and decreased at greater depths. Figure 2 depicts the relationship between dissolved oxygen concentration and dissolved N_2O concentration (top) or nitrogen isotope ratio in N_2O (bottom).

According to the nitrogen isotope ratio ($\delta^{15}N$ referred to atmospheric N_2 standard), dissolved N_2O can be categorized into two groups; one is depleted in ^{15}N (average $\delta^{15}N = 5.2 \pm 1.3$‰) relative to that in equilibrium with atmospheric N_2O (8.0‰ as indicated by the dotted line in Fig. 2), and the other is enriched in ^{15}N (average $\delta^{15}N = 12.6 \pm 1.1$‰). The former was found invariably at depths where the oxygen concentration was relatively high, while the latter occurred at depths where the oxygen concentration was extremely low and the N_2O concentration almost the same as or somewhat lower than the level in equilibrium with air estimated from the solubility data of N_2O (ref. 22). The high concentration of dissolved N_2O observed above the oxygen minimum layer can be attributed to the production of N_2O associated with nitrification[18–20]. Our ^{15}N data support this inference, because we (N.Y. and S.M.,

*As for the maritime air, Rasmussen and Pierotti[25] reported the N_2O content to be between 315 and 330 parts per 10^9 (p.p.b.). On the other hand, Weiss *et al.*[26] proposed that it was 302.8 ± 0.6 p.p.b. for this sampling time.

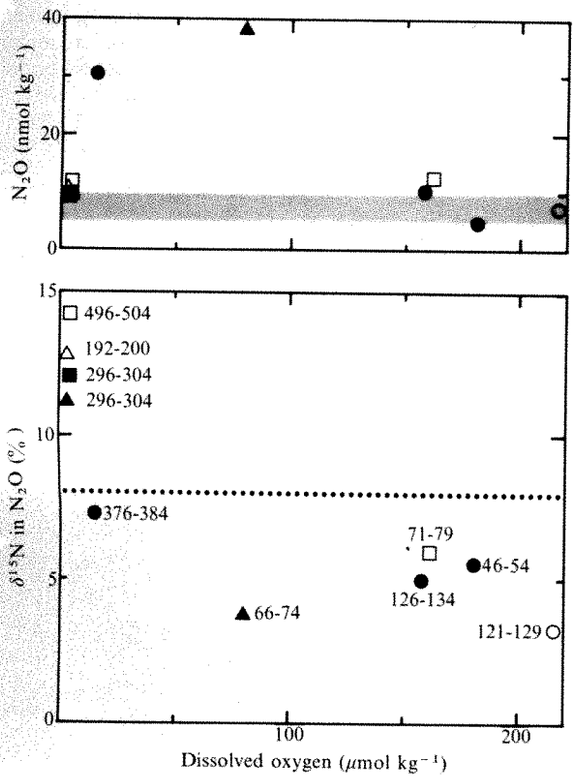

Fig. 2 Relationship between dissolved oxygen concentration and N_2O concentration (top) or nitrogen isotope ratio in N_2O (bottom) in the subsurface waters of the eastern tropical Pacific Ocean. Numerical values represent depth ranges where the water samples were collected. Symbols: ○, station 9; △, station 13; □, station 16; ●, station 19; ▲, station 25; ■, station 11′. Sampling date and station location are given in Table 1 except for station 11′ (18 January 1983, 17°27′ N and 116°58′ W). Oxygen data presented in the cruise report[21] were used. A shaded bar (top) and a dotted line (bottom) refer to N_2O concentration and $\delta^{15}N$ in N_2O in equilibrium with atmospheric N_2O (averages in Table 1), respectively. The range of equilibrium concentration corresponds to the range of temperature and salinity of the seawater samples; from 8.58 °C and 34.626‰ to 28.21 °C and 35.048‰. The nitrogen isotope fractionation factor in the process of dissolution of N_2O in seawater is substituted for that in pure water which is 0.9992 (N.Y. and S.M., unpublished) in this temperature range; this means 0.8‰ enrichment of ^{15}N in the aqueous phase.

unpublished) have found a great depletion of ^{15}N down to −66‰ in the product N_2O relative to the initial reactant ammonium during nitrification by *Nitrosomonas europaea*. The lighter isotope was preferentially used to produce N_2O. Actually, excess N_2O (N_2O concentration observed − N_2O concentration in equilibrium with air at given temperature and salinity) was linearly correlated with AOU (apparent oxygen utilization) (data not shown), as observed by Yoshinari[9], Elkins *et al.*[11] and Cohen and Gordon[13].

The ^{15}N enrichment in N_2O in the oxygen minimum zone can also be explained by the isotope ratio of the nitrate source and by the isotope fractionation associated with denitrification. Cline and Kaplan[23] demonstrated that nitrate in the oxygen-deficient waters of the eastern tropical North Pacific is highly enriched in ^{15}N. N_2O enriched in ^{15}N may result from nitrate enriched in ^{15}N. Nitrous oxide enriched in ^{15}N may also be produced by the mode of reaction kinetics associated with denitrification, as observed in the case of nitrite by Blackmer and Bremner[24]. ^{15}N enrichment in N_2O caused by isotope fractionation in reduction of N_2O is also likely. We (N.Y. and S.M., unpublished) have found nitrogen isotope fractionation factors of up to 1.027 in the reduction of N_2O by *Pseudomonas denitrificans*, where the lighter isotope was favoured in the N_2 produced. In fact, N_2O concentrations in extremely oxygen-depleted waters were far less than that expected from AOU.

The average nitrogen isotope ratio of N_2O in maritime air collected on the same cruise over the Pacific Ocean (Table 1) was 7.2 ± 1.1‰. This average was higher than that of dissolved N_2O in the subsurface layer above the oxygen minimum zone, but slightly lower than that of land surface air collected in Japan (8.1 ± 1.0‰)[17]. The observed difference suggests that the subsurface layer of the sea seems to emit ^{15}N-depleted N_2O and consequently lower ^{15}N content of N_2O in the maritime air. The results described here are still too premature to discuss this topic in further detail. However, we emphasize that nitrogen isotope studies have the potential to answer such questions.

We thank the officers and crew members of the RV *Hakuho Maru* and the scientists aboard the KH-82-5 cruise for cooperation, especially Mr H. Otobe for assistance in air and water sampling. Our special thanks also to Asahi Breweries Ltd, Japan for allowing us to use the stainless steel tanks for N_2O extraction.

Rare earth element fluxes and geochemical budget in the eastern equatorial Pacific

Kim Murphy & Jack Dymond

College of Oceanography, Oregon State University, Corvallis, Oregon 97331, USA

Rare earth element (REE) patterns and flux measurements of sediment traps, sediments, and nodules from the eastern tropical Pacific demonstrate the dominance of REE supply to the sea floor by particle settling. Quantitative partitioning of the particle flux reveals that biogenic debris is the major REE carrier in shallow depths; however, the labile particles are surpassed in importance by alumino-silicate particles at greater depths. Regeneration of biogenic-associated REE appears responsible for La/Ce variations in the particle flux with depth, and provides the primary source of REE accreted by nodules.

Studies of the fractionation of individual REE from one another have provided insight into the geochemical behaviour of REE in the marine environment[1–3]. Ce, because of its unique preference for the 4+ state in seawater, may be more readily adsorbed onto water column particles[4] and incorporated into deep-sea sediments and ferromanganese nodules[5]. Thus, the preferential adsorption of Ce may explain its depletion in seawater relative to the trivalent REE[6,7]. Seawater is also enriched in the heavy REE (HREE), possibly as a result of the greater stability of aqueous complexes formed by HREE, leaving seawater relatively enriched in these elements[6,7].

Although previous studies have used REE fractionation to emphasize the importance of a particle-derived source of REE to sediments and nodules (ref. 2 and others therein), ours are the first reported measurements of the particulate REE flux. We present the REE contents, patterns and fluxes of sedimentary samples from the Manganese Nodule Program (MANOP) site H (6.5° N, 93° W) in the eastern equatorial Pacific in order to establish the REE geochemical budget for this site. In addition, we partition particulate REE into biogenic and detrital components. Decomposition of organic matter and dissolution of opal and carbonate can release REE which are sorbed to other particle surfaces or lost to seawater. Since such material decomposes more readily than detrital phases, the associated REE are more available for uptake by nodules and other authigenic phases.

Samples for this study were analysed for La, Ce, Nd, Sm, Eu, Tb, Yb and Lu by instrumental neutron activation[8] (Table 1). Analytical precision for the REE was within 10% for all samples, except for Nd and Tb which have peak interferences. Interferences due to U were negligible.

Figure 1 shows the REE abundance patterns of site H samples normalized to that of world average shale[5]. Different sample types exhibit large variations in absolute concentration in the order: ferromanganese crust > nodule tops > sediment > nodule bottoms > sediment traps. Nonetheless, the general pattern for all samples is similar to that of site H bottom water (Fig. 1). All samples exhibit the Ce depletion and HREE enrichment typical of seawater. This does not, however, necessarily imply accretion by precipitation from seawater. Site H ferromanganese crust, dredged with basalts and isolated from sediment contact, is thought to form by direct precipitation from bottom water (hydrogenous accretion)[9]. This crust has the smallest Ce anomaly and least resembles the seawater pattern of all the site H samples (Fig. 1). In contrast, similar crusts of probable hydrogenous origin have large positive Ce anomalies[10].

The REE patterns of site H nodules are unlike those of most deep-ocean nodules, which have positive Ce anomalies[1,2]. Nodules from the Bauer Basin of the south equatorial Pacific, however, have negative Ce anomalies[11,12] which are believed to result primarily from hydrothermal iron oxyhydroxides possessing a seawater-like REE pattern[12]. The negative Ce anomalies of site H nodules may also indicate hydrothermal influence, since site H and the Bauer Basin are both within 1,000 km of the East Pacific Rise.

Accumulation rates (mass added per unit time per area) were calculated for site H crusts, nodule tops and bottoms, sediments, and trap material in order to provide a more complete understanding of REE cycling (Fig. 2). Distinctions between nodule tops and bottoms were based on texture and major element composition[9]. Results of site H flux calculations for Oregon State University single cone[13] and Soutar double cone[14] sediment traps deployed from September 1980 to October 1981 reveal increases in the total particle flux[15] with depth. In addition, the increase in the particulate REE concentration with depth (Fig. 1) results in a substantial increase in REE flux with

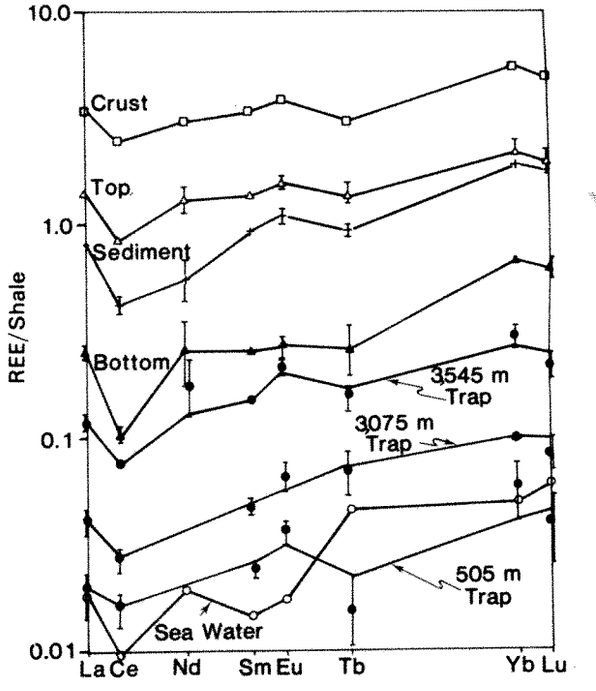

Fig. 1 REE abundances in ferromanganese crust, nodule top and bottom, sediment, sediment traps and bottom water normalized to the world average shale[1]. Seawater data are for deep water from the Guatemala Basin near site H[20] and are multiplied by a factor of 10^3. Values without error bars have errors within symbol size. Values not shown were below the detection limit or had associated errors >50%.

depth (Fig. 2). This may be caused by adsorption of REE onto particulate debris as it falls through the water column and/or additional sources of REE-rich particles at depth. Within the upper 1,500 m of the water column, there is a substantial increase in REE particulate flux with depth. Such an increase has been noted in other oceanic locations and may be due to lateral transport of material[16], particle aggregation[17], or zooplankton feeding dynamics[18]. Below 1,500 m REE flux increase is gradual until within approximately 500 m of the bottom. Below this, there is a sharp increase in apparent flux which is due to resuspension of bottom material[13]. Therefore, in calculating sediment trap REE fluxes to the sediment–water interface, an extrapolation of fluxes between 1,465 m and 3,075 m depths was used to avoid the influence of local resuspension which produces an artificial flux increase in near-bottom traps.

Comparison of the extrapolated trap flux to the elemental accumulation rate in the sediment reveals that the total REE particulate flux accounts for approximately 85–100% of the REE preserved in site H sediments (Fig. 2). Hydrogenous precipitation, presumably represented by accretion in ferromanganese crust, is another potential source of REE to the sediments. However, since REE accumulation in crust accounts for less than 7% and 1% of the REE accumulation rates in nodules and sediments, respectively (Fig. 2), the contribution from the hydrogenous source appears relatively insignificant, and particulate debris is apparently the major source of REE to site H nodules and sediments. Near-bottom enrichments of REE in the North Atlantic[3] suggest that REE are released by regeneration of labile biogenic particles at the sediment–water interface[17]. However, our geochemical balance (Fig. 2) implies that REE at H are strongly retained by sedimentary phases. Nonetheless, the range in bulk sedimentation rate (Fig. 2), the resuspension assumptions of the flux calculations, and uncertainties involved in comparing a single year of trap data with the sediment record, limit the precision of the extrapolated and observed flux comparison. For several refractory elements, such as Al, the agreement between sediment accumulation and extrapolated particle flux is within 10%, while labile elements, such as Cu, show 40–50% regeneration at the sediment–water interface[15]. Results for the REE clearly show that a particulate source is the major supply to site H sediments and that the fraction of REE regenerated from particles at the sea floor is small.

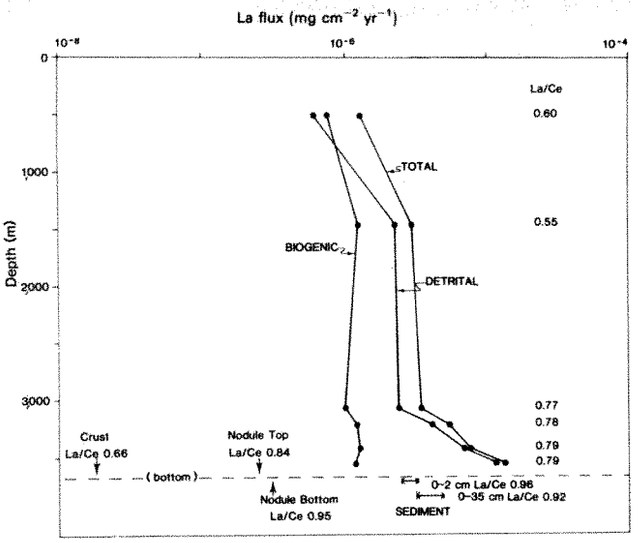

Fig. 2 La fluxes and La/Ce ratios of site H samples. Regression-derived REE concentrations and ratios: (1) biogenic: La = 0.5 p.p.m., Ce = 1.0 p.p.m., La/Ce = 0.50 ($r^2 = 0.99$); (2) detrital: La = 40.5 p.p.m., Ce = 43.0 p.p.m., La/Ce = 0.93 ($r^2 = 0.98$). Accumulation rates of REE in crusts, nodule tops, nodule bottoms, sediments and sediment traps were calculated using $A = SC\rho$; where A is the flux or accumulation rate of an element in a sample; S is the bulk growth rate, sedimentation rate, or flux applying to crusts/nodules, sediments and traps, respectively; C is the concentration of an element in a sample; and ρ is the dry bulk density of nodules, crusts or sediments. Biogenic and detrital fluxes were derived from linear programming. Crust growth rates are estimated at 1 mm per 10^3 yr (ref. 25). Nodule top/bottom growth rates were determined by refs 26 and 27. Sediment accumulation rate ranges are based on sedimentation rates of 0.45 cm per 10^3 yr (ref. 28) and 0.65 cm per 10^3 yr (ref. 29). Dry bulk density values of 1.35 g cm^{-3} (ref. 24) and 0.22 g cm^{-3} (K.M., unpublished data) were used for crust/nodules and sediment, respectively.

To clarify further the REE budget at site H, sediment trap and surface sediment samples were partitioned into end-member components using normative analysis. Weight fractions of carbonate, opal, organic matter and ferromanganese precipitates, which best account for the abundance of 13 elements (organic C, P, N, Al, Si, Ca, Ti, Mn, Fe, Cu, Ni, Zn and Co) in 27 annual and seasonal trap and surface sediment samples from MANOP sites H and M (9° N, 104° W), were estimated by linear programming[19]. The carbonate, opal and organic matter fractions were combined as 'biogenic material'. Regression lines were determined between the measured REE content and the percentage of biogenic or detrital component. Extrapolation of the line to 100% of each component allows estimation of the concentrations of pure end-members (Fig. 2). The REE flux from each source can be computed from the end-member fractions in each sample and the regression-derived REE end-member concentrations (Fig. 2). The model, of course, assumes biogenic and detrital components have a constant composition. Since the REE content of particles may result from scavenging, compositional variability with depth may occur which would add uncertainty to the normative analysis.

Table 2 shows that the sum of the regression-derived biogenic and detrital fluxes approximates the measured La flux within 10%, for five out of six traps. The biogenic and detrital fluxes account for nearly all the REE flux throughout the water column, while the ferrogmanganese end-member, possibly representing hydrothermal influence, is relatively insignificant in all traps (K.M. and J.D., unpublished data). The results demonstrate that the biogenic REE flux is dominant in the upper 750 m of the water column but is surpassed by the detrital flux below this depth (Table 2, Fig. 2). Within the bottom 500 m, resuspension of detrital material, which is relatively enriched in the

Table 2 Percentage of total measured La flux explained by end-members in annual traps

Trap depth (m)	Biogenic (%)	Detrital (%)	Difference between measured and calculated flux* (%)

3,415†	17	91	8
3,545†	9	86	5

* Calculated flux = regression-derived biogenic + detrital fluxes.
† Resuspension influenced[13].

sediments, distorts the true flux of the two components. Nevertheless, the detrital REE flux increases gradually with depth, while the biogenic REE flux decreases slightly. This trend probably results from the decomposition and dissolution of biogenic debris as it falls through the water column, combined with an increase in the detrital fraction due to resuspension at depth. The observation that the biogenic REE flux comprises 30–60% of the total flux to site H sediment traps not influenced by resuspension (Table 2) is consistent with the suggestion that REE are associated with biogenic particles[3].

The La/Ce values suggest that some fractionation occurs between Ce and the trivalent REE. This ratio is a more direct means of comparison and has greater precision than the Ce anomaly, particularly for sediment traps which have low REE abundances and greater analytical errors for Nd (Fig. 1). The biogenic component of trap debris, with a La/Ce ratio of 0.50, is enriched in Ce relative to the detrital end-member, with a La/Ce of 0.93 (Fig. 2). Both components, however, are enriched in Ce relative to La, and although deep-ocean nodules have been claimed to be responsible for the REE pattern of seawater[1], a quantitative accounting of the Ce enrichments in these phases could also explain the negative Ce anomaly of seawater. The La/Ce ratio of Guatemala Basin bottom water near site H is approximately 2.0 (ref. 20), and North Atlantic waters below 200 m also have La/Ce ratios ranging between 1.0 and 2.4 (ref. 3). Therefore, the biogenic component at site H is enriched in Ce relative to La when compared with seawater. Elderfield and Greaves' study in the North Atlantic[3] revealed surface water enrichments of Ce that were high compared with the trivalent REE, presumably due to preferential diffusion of Ce from reducing continental margin sediments[21] and advection of margin waters. Since site H could also receive excess Ce by advection from the slope region, the extent of La/Ce fractionation by biogenous debris is uncertain without surface water REE data.

We find a consistently lower La/Ce ratio for traps from the upper 1,500 m (La/Ce ≈ 0.6) compared with La/Ce values of the near-bottom traps (La/Ce > 0.75) (Fig. 2). This trend may result from the aforementioned input of Ce mobilized from near-shore anoxic sediments. It is hypothesized that Ce, like Mn (refs 22, 23), is solubilized at locations where the oxygen minimum intersects the continental margin. The unusually high Mn content of site H trap particles[15] implies that near-shore reduction and subsequent remobilization of Mn influence the composition of particles at this location. Alternatively, the La/Ce increase with depth may be due to decomposition of Ce-enriched labile biogenic particles that release REE to seawater and increase the influence of the detrital fraction which is relatively depleted in Ce. Trapping of resuspended sediments in the deepest traps would also result in higher La/Ce, since the La/Ce of sediments is about 1.0. The 3,075 m trap, which is more than 500 m above the bottom, is believed to be free of resuspended material, however[24]. Since it, too, has elevated La/Ce compared with the near-surface traps, it appears that

resuspension is not the sole explanation for the La/Ce increase with depth. Moreover, the La/Ce of the deepest traps (0.8) does not match the La/Ce ratio of site H sediments (1.0). Fractionation of the REE, which apparently occurs during sediment diagenesis, may explain the increased La/Ce of site H sediments. During periodic, highly reducing conditions, Mn is remobilized within the sediments and conveyed to nodule bottoms[9]. Under such conditions, Ce may be reduced to its trivalent state and mobilized to nodules, and possibly into the bottom water[21]. Although the trivalent REE should also be mobilized under these conditions, enhanced Ce release could result if the Mn-rich phase that dissolves is also enriched in Ce relative to the other REE.

Thus, sediment trap material, sediments and nodules from the eastern tropical Pacific all have seawater-like REE patterns. Flux calculations imply that particles can account for most, if not all, of the REE supply to site H sediments and can easily account for REE accumulation rates in nodules. Breakdown of the particulate flux into end-member components discloses the importance of biogenic material as well as detrital particles in conveying REE to the ocean bottom at site H. The La/Ce ratios of the biogenic and detrital trap components and traps throughout the water column confirm the importance of both components in supplying REE to sediments and nodules and indicate the release of REE from labile biogenic components. Although biogenic and detrital material both contribute REE to sediment traps, it is the biogenic fraction which undergoes decomposition and dissolution reactions, that probably conveys the majority of REE to nodules.

We thank Dr D. Z. Piper for providing the nodule samples used in Fig. 1, Dr K. Fischer for the use of sediment trap data, Drs R. Schmitt, M. Lyle and R. Collier for their comments and constructive criticism of the manuscript, R. Conard for technical assistance, and N. Pisias' for help in computer-based data analysis techniques. This work was supported by NSF grant OCE-8026744.

Apparent changes in the climatic state of the deep North Atlantic Ocean

Determination of any long-term changes in the large-scale characteristics of the deep ocean circulation would be an important clue in understanding the climatic interactions of the ocean and atmosphere. In the summer of 1981, the RV *Atlantis II* reoccupied two transatlantic sections at nominal latitudes of 24°30′ N and 36°16′ N with a conductivity–temperature-depth instrument (CTD). One purpose of the work was to make a comparison with previous surveys conducted during the International Geophysical Year (IGY)[1], when sections were obtained in October 1957 and April–May 1959. We report here that significant warming occurred in an ocean-wide band from 700 m to 3,000 m with a maximum temperature difference of 0.2 °C. These changes are sufficient to expand the water column by several centimetres. The historical temperature–salinity curve was apparently unchanged. Interannual changes in local water mass characteristics have been proposed previously[2,3]. Perhaps it would be most surprising if no changes were seen to occur. What remains obscure is the significance of these changes and the extent to which they represent long-term climate trends, or merely the minor and random fluctuations to be expected in any complex fluid system.

To make a direct comparison of temperature in the two investigations, we have interpolated the data to common locations (excluding segments at the ends where the lines did not coincide). A fine mesh was generated (grid points over 40 m vertically and every 10 km horizontally) using the technique of objective mapping[4,5]. Subtraction of IGY temperatures from the 1981 temperatures gave temperature differences, but maps of temperature difference have strong mesoscale features that make it difficult to pick out large-scale trends. To suppress the small scales, a horizontal gaussian filter 1,000 km wide was applied to produce smoothed maps of temperature difference (Fig. 1*a* (24° N) and *b* (36° N)).

The most prominent feature of the temperature difference maps is an ocean-wide band of warmer water at middle depths of both latitudes. This band is much thicker and more intense in the western basin, where it extends from a depth of a few hundred metres to greater than 3,500 m. Relative to the IGY survey, mid-depth isotherms in the 1981 survey were lower overall and were tipped downward towards the west. Other strong features are seen in Fig. 1, such as the large area of negative temperature difference at 36° N, centred at about 500 m, just west of the mid-Atlantic ridge. However, these other features are not clearly similar at the two latitudes (they appear in different temperature ranges) and therefore cannot be said to be of ocean scale. Features high in the water column are likely to result from local processes while characteristics of the deep water are determined at remote source regions at high latitudes[6].

Figure 2 shows temperature difference averaged across the width of the ocean. The average warming begins at a depth of 500–700 m and extends to 3,000 m with a peak of about 0.2 °C at 1,000–1,500 m. By computing an average vertical temperature gradient, temperature difference was converted to an equivalent vertical displacement of isotherms (the vertical temperature gradient is much greater at 1,000 m than at 2,000 m). Vertical displacements were approximately 20 m and 100 m

downward at 1,000 and 2,000 m respectively. The displacement at 2,000 m is large enough to be seen in a visual comparison of temperature maps from the 1981 and IGY sections, noting, for example, a drop of about 100 m in the 4 °C isotherm. Below 3,000 m, average temperature differences were small but tended to be negative. Above 700 m, a strong but thin band of negative difference is seen at 24° N at about 200 m and at 36° N a thicker band extends from 100 to 700 m. This upper-ocean cooling trend has been noted previously[7] at the Panuliris station (32° N, 64° W). At 24° N, the positive temperature difference at mid-depth dominates the vertical profile. Excluding the upper 100 m, where seasonal effects are important, the 1981 section at 24° N is 0.03 °C warmer than the IGY section. At 36° N, the positive differences are balanced by the negative ones and the total average temperature is nearly unchanged.

The tendency in salinity changes (not shown) was to maintain the historical temperature/salinity correlation; that is, positive temperature differences were usually accompanied by positive salinity differences. Because we observe greater vertical displacements in isotherms at some levels than at others, changes in the volumes occupied by different water masses must have occurred.

To study the expansion and contraction of water masses, the ocean was divided into six layers separated by surfaces of constant potential temperature. The six layers, chosen on the basis of earlier work[8], are shown in Table 1 with the area occupied by each of these water masses in each of the four sections. At both 24° N and 36° N there is an expansion in bottom water (<2 °C), a contraction in deep water (2–4 °C) and an expansion in middle and lower thermocline water (4–12 °C). Summing the change in deep and bottom water, the net contraction of water cooler than 4 °C lowers the isotherms of the middle and lower thermocline, consistent with the observation of warmer water at mid-depth.

In a discussion of error sources in the preceding calculations, measurement and mapping errors (negligible for present purposes) are included, as well as errors caused by the presence of short time scale eddies. The latter were found to be the largest error source, with a single intense eddy able to perturb the 1,000 m temperature by about 2 °C over 200 km, while the perturbation at 2,000 m is about 0.3 °C. Averaged over a 5,000 km basin, these estimates result in a bias of 0.08 °C at 1,000 m and 0.01 °C at 2,000 m. Because we observed the same pattern of change at both 24° and 36° N, and because the 0.1 °C
